Salvatore R. Maddi, the son of Sicilian immigrants, was born in New York in 1933. He received a PhD in clinical psychology with honors from Harvard University in 1960. Having taught at the University of Chicago (1960–1986), and the University of California, Irvine (1986–2015), he has developed the hardiness approach, that shows how people can develop the courage, motivation, and capabilities to turn stressful circumstances into growth opportunities. He has won many awards, the latest of which is the 2012 American Psychological Foundation Gold Medal.

Chloe R. Maksoudian studies in the Psychology and History Departments at La Sierra University and is particularly interested in history, law, and forensics. She works as a research assistant in two different faculty laboratories – one in developmental psychology and one in neuroscience.

David Matsumoto is professor of psychology and director of the Culture and Emotion Research Laboratory at San Francisco State University. He has studied culture, emotion, social interaction and communication for over 30 years. His books include *Culture and Psychology,* the *Cambridge Dictionary of Psychology,* and *Cross-Cultural Research Methods in Psychology*.

Leslie R. Martin is professor of psychology at La Sierra University and holds additional appointments at the University of California, Riverside and Loma Linda University. Much of her research over the past 20 years has addressed the links between personality, psychosocial factors, health outcomes, and mortality risk. She has co-authored several books including *Health Behavior Change and Treatment Adherence: Evidence-based Guidelines for Improving Healthcare* (Oxford University Press), *The Longevity Project* (Hudson Street Press) and is co-editor of *The Oxford Handbook of Health Communication, Behavior Change, and Treatment Adherence*.

Sandra Matz (PhD, Cambridge University, 2017) is an assistant professor of management at Columbia University. Her research aims at understanding how psychological characteristics influence real-life outcomes in a number of business-related domains (e.g. financial well-being, consumer satisfaction or team performance), with the goal of helping businesses and individuals to make better decisions.

Laurie "Lali" D. McCubbin (PhD, University of Wisconsin–Madison, 2003) is an associate professor in counseling psychology at the University of Louisville and an indigenous/multiracial scholar (Native Hawaiian/Japanese/European American). She is a member of Division 7 (Developmental Psychology), 17 (Society of Counseling Psychology), 35 (Psychology of Women), 45 (The Society for the Psychological Study of Culture, Ethnicity, and Race and Asian American Psychological Association and Society for Indian Psychologists). She also served as chair for the Committee for Children, Youth and Families for the American Psychological Association. She is currently the executive director of the Resilience, Adaptation and Well-Being Project (www.mccubbinresilience.org) where she oversees measures related to family resilience and family resilience models.

J. Douglas McDonald (Spotted Hawk) is a professor and director of the Indians into Psychology (INPSYDE) program within the psychology department at the University of North Dakota (UND). A member of the Oglala Lakota tribe, he has mentored over

50 American Indian graduate students while serving as president of the Society of Indian Psychologists (SIP), APA Division 45, served on three APA boards, as well as the Council of Representatives. His research focuses on cross-cultural psychological applications as well as men and masculinity issues. An avid outdoorsman, he lives in Grand Forks with his wife Cher and cat, Moagie.

Geordie McRuer (PhD, University of Toronto, 2014) is the founding partner of Bastet Strategy, which provides consulting and leadership development services to help organizations improve their ability to manage change. His most recent research explores the relationship between feedback and creativity.

Andrea Mejia is a graduate student studying neuropsychological assessment in the clinical psychology program at the University of Florida. She holds a Masters degree in Psychology from the University of North Carolina Wilmington.

William Ming Liu, PhD, is professor and program coordinator of Counseling Psychology at the University of Iowa. His research interests are in social class and classism, men and masculinity, White supremacy, and multicultural competencies. He is an editor of the *Handbook of Multicultural Competencies in Counseling and Psychology* (Sage, 2003), an editor of *Culturally Responsive Counseling with Asian American Men* (2010, Routledge), the author of *Social Class and Classism in the Helping Professions: Research, Theory, and Practice* (2011, Sage), and the editor of *Handbook of Social Class in Counseling* (2013, Oxford University Press). He is the editor for the *Psychology of Men and Masculinity*.

Jeffrey S. Mintert (MS, Arizona State University, 2012) is a third-year doctoral student in counseling psychology at Arizona State University. His research interests pertain to examining bullying in adolescence using a social-ecological model. Additionally, he is interested in identity-based bullying, specifically among LGBT youth. He recently presented a symposium titled "What are adult perceptions of the causes of the phenomenological issue of bullying? A qualitative analysis" at the 2016 American Psychological Association (APA) Convention in Denver, CO.

Jeffery Scott Mio is a professor in the Psychology Department at California State Polytechnic University, Pomona, and he is the executive officer of the Western Psychological Association. He has published numerous books, including *Multicultural Psychology: Understanding our Diverse Communities* (Oxford University Press*), Culturally Diverse Mental Health: The Challenges of Research and Resistance* (Brunner-Routledge), and *Warring with Words: Metaphors and Narratives in Politics and International Relations* (Psychological Press). He is interested in the teaching of multicultural issues and in how metaphors are used in political persuasion.

Alejandro Morales is an assistant professor of psychology at California State Polytechnic University, Pomona, where he teaches courses on abnormal psychology, intimate relationships, basic counseling skills, and couples psychotherapy. He received his doctorate in counseling psychology from the University of Nebraska–Lincoln. Dr. Morales conducts research on the areas of language brokering in immigrant families and the psychosocial adjustment of Latina/o sexual minorities.

Thomas P. Mounsey (MA, Long Island University, Brooklyn) is a graduate student in the department of psychology at Long Island University, Brooklyn working toward his doctoral degree.

Elias Mpofu, PhD, DEd, is professor of rehabilitation and health services at the University of North Texas. He is editor of a volume of *Counseling People of African Ancestry* (2010; Cambridge University Press). He has implemented an integrative test development and adaptation model for use in emerging country settings (*International Perspectives in Psychology: Research, Practice, and Consultation, 3*(2), 106–122. doi:10.1037/ipp0000015).

Lisa Murphy received her MA in criminology from the University of Ottawa in 2009. During her master's, Mrs. Murphy worked as a research analyst at the Royal Canadian Mounted Police's (RCMP) National Child Exploitation Coordination Centre. She left her role with the police to reorganize the assessment laboratory as the Sexual Behaviours Clinic (SBC) Coordinator. Mrs. Murphy has conducted upwards of 1,000 assessments at the SBC and has a keen interest in developing methods for multisite standardization of assessment. She has published and presented extensively on assessment, treatment, and mechanisms of community-based management of sex offenders.

Kevin Nadal, PhD, is a professor of psychology at the City University of New York (CUNY). He is the president of the Asian American Psychological Association, the founder of the LGBTQ Scholars of Color Network, and the first person of color to serve as executive director of the Center for LGBTQ Studies at the CUNY Graduate Center. A national trustee of the Filipino American National Historical Society and a contributor to the *Huffington Post*, he has published over 100 works on multicultural issues, including eight books such as *Filipino American Psychology* and *Microaggressions and Trauma*. A graduate of Columbia University, he has published extensively on Microaggression Theory with his mentor, Dr. Derald Wing Sue.

Jeanne Nakamura (PhD, University of Chicago) is associate professor of psychology and co-director of the Quality of Life Research Center, Claremont Graduate University. Her research and writing address motivation and engagement during adulthood, good work, the formative influences of mentoring and the formation of good mentors, and positive aging. She has studied phenomenological features of the flow state such as effortless attention and hypoegoism as well as dispositional flow proneness, and is particularly interested in the relations of flow to meaning and human development. She is the co-author of *Good Mentoring* (2009) and co-editor of *Applied Positive Psychology* (2011).

Revital Naor-Ziv is a researcher and lecturer in the Department of Criminology, Bar-Ilan University, Israel. Her ongoing interest is in the study of neuro-cognitive functioning, risk-taking behaviors, and psychopathology during adolescence. Her research combines cognitive, personality and neuropsychological approaches to the study of impulsivity, sensation-seeking, executive functions, emotion regulation, theory of mind and the neural basis of empathy and risk-taking behaviors, such as eating disorders and conduct disorders. She has recently published an article (with Joseph Glicksohn) in *Developmental Neuropsychology*, looking at cognitive deficits as risk factors for developing eating disorders during adolescence.

Mariya Narizhnaya, PsyD recently graduated from the University of Hartford. She is currently a postdoctoral psychology resident at the Miami VA. She completed an internship at the Brooklyn VA in 2019. For her doctorate dissertation, she explored coping skills for work-related stress in immigrants from the former Soviet Union currently living and working in the United States. Her goal is to contribute to research on immigrant mental health. Mariya's clinical interests include culturally informed therapeutic interventions, trauma stabilization psychotherapies, and brief interventions for health concerns and sleep disorders.

Sami Nesnidol is a graduate student at Bowling Green State University studying industrial organizational psychology. Her research interests include the application of judgment and decision-making to the areas of employee selection and organizational sustainability.

Allen M. Omoto, PhD, is a professor of psychology and an administrator at Claremont Graduate University in Claremont, California. His research focuses on the social and psychological aspects of prosocial behavior, volunteerism, and civic and political engagement. He also conducts research on a variety of social issues, including environmentalism, HIV, and lesbian, gay, and bisexual concerns.

Deniz S. Ones (PhD, University of Iowa) is a distinguished professor at the University of Minnesota. She currently serves on nine editorial boards and has served as in chief of the *International Journal of Selection and Assessment* (2001–2006). She has edited over a dozen book and journal special issues. She is a fellow of Divisions 5 (Evaluation, Measurement, and Statistics), 8 (Personality and Social Psychology), and 14 (SIOP)) of the American Psychological Association as well as a fellow of the Association for Psychological Science. Her research focuses on assessment of individual difference constructs (integrity, personality, ability) for the prediction of job performance, especially counterproductive work behaviors. She has published over 175 articles and chapters that have been cited over 15,000 times (h-index = 56).

Atsushi Oshio (PhD, Nagoya University, 2000) is a full professor of psychology at Waseda

University, Tokyo, Japan. His research interests include assessment, structure, and development of personality traits, adaptive/maladaptive processes with personality traits and thinking styles. He is the author of 18 Japanese books and more than 150 research articles in Japanese and English.

Victoria L. Pace, PhD, is an associate lecturer and director of the MS in Industrial/Organizational Psychology program at the University of Central Florida. She researches personality in the workplace, including development and validation of measures, administration of tests, and use of results for prediction of performance as well as for developmental purposes.

Cody D. Packard, MA, is a PhD student in social psychology at Claremont Graduate University. His research interests focus on environmental attitudes and predicting pro-environmental behavior, as well as how reactance may inhibit pro-environmental and prosocial behavior.

Ronald S. Palomares, PhD, is a licensed psychologist (Texas) and an assistant professor at Texas Woman's University, where he serves as the director of the Doctoral School Psychology program. Dr. Palomares serves on the Texas State Board of Examiners of Psychologists (TSBEP), the Commission for the Recognition of Specialties and Proficiencies in Professional psychology (CRSPPP) in the American Psychological Association (APA), and is a fellow of the APA. He has several publications and numerous presentations focused on military-connected children and families, telepsychology, and resilience-building skills. Dr. Palomares has also worked as a school psychologist, psychologist for the Dallas county hospital, and on staff at the American Psychological Association where he focused on policy and advocacy issues related to children and families. More recently, he provided direct psychological relief work in Nepal (2015) and conducted psycho-educational training on PTSD in South Sudan (2016).

Joanna Pantelides, B.S., graduated from the Schreyer's Honor College at The Pennsylvania State University, having majored in psychology with a biological and evolutionary sciences emphasis and a minor in sociology. At Penn State she served as the lab manager in Dr. Levy's Laboratory for Personality, Psychopathology, and Psychotherapy Research After graduation Joanna worked as a research assistant at the Joan and Sanford I. Weill Medical College of Cornell University. Joanna will be entering doctoral training in clinical psychology at Long Island University – Brooklyn Campus in the fall of 2020. She intends to pursue a career in research and practice.

Matthew A. Pardo, BA, is a candidate for a master's degree at DePaul University. Mr. Pardo is currently working with Dr. Ferrari on the areas of: psychological home, spiritual retreats for the homeless, and sentencing decisions based on perspective-taking and race.

Katharine R. Parkes, PhD, held the post of reader in applied psychology, Department of Experimental Psychology, University of Oxford until 2014; now retired, she remains active in research and publication. Her interest in stress and coping stems from the 1970s when she worked with Richard Lazarus at UC Berkeley. Her later research focuses on psychosocial work characteristics, coping, individual differences, affective well-being and physical health. She has published widely in these areas, and is a fellow of the British Psychological Society. A recent publication is K. R. Parkes (2016) "Age and work environment characteristics in relation to sleep: Additive, interactive and curvilinear effects." *Applied Ergonomics, 54,* 41–50.

Konstantinos V. Petrides is director of the London Psychometric Laboratory and professor of psychology and psychometrics at University College London (UCL). He is the developer of the family of Trait Emotional Intelligence Questionnaires (TEIQue), which are used in commercial and scientific research applications globally. Konstantinos lectures internationally on his theory of psychobionomy, personality, and psychometrics. The London Psychometric Laboratory can be accessed at www.psychometriclab.com.

Craig P. Polizzi is a clinical psychology doctoral student at Binghamton University. He has collaborated on randomized controlled trials investigating integrative and complementary interventions for veterans with Posttraumatic Stress Disorder (PTSD). He has also participated in trials examining educational interventions promoting self-regulation in children.

His current research focuses on clarifying the relations among acceptance, mindfulness, emotion regulation, and resilience and on elucidating how each functions as a self-regulation strategy. Recently, he has served as principal investigator on a longitudinal study examining novel ways to facilitate the salutary effects of mindfulness meditation.

Matthew Ponsford received his PsyD in clinical psychology from Antioch University Seattle. His research and clinical interests include the social construction of gender and the self, the interaction between online and offline identities in individuals who play online video games, and the formation of community in virtual worlds.

Jack L. Powell, PhD, is a professor of psychology and chair of the Department of Psychology at the University of Hartford. His research interests are in the areas of judgment, decision-making, and the psychology of religion and spirituality.

Antonio E. Puente, PhD, holds a BA from the University of Florida and a PhD from the University of Georgia. He is professor of psychology at the University of North Carolina Wilmington and holds visiting professorships at the Universidad de Granada (Spain) and UCLA. He has been president of several societies including the National Academy of Neuropsychology and the Society for Clinical Neuropsychology and was the 125th president of the American Psychological Association.

Lena C. Quilty (PhD, University of Waterloo, 2006) is a senior scientist in the Centre for Addiction and Mental Health and assistant professor, University of Toronto. She is a registered clinical psychologist and certified cognitive behavioral therapist. Her research interests include personality and cognitive moderators and mediators of treatment outcome in depression and addiction, with a focus on incentive motivation and impulsivity. She has co-authored over 100 scholarly publications, including investigations of the role of personality, cognition, and interpersonal processes across psychosocial and biological treatments. PubMed-listed publications can be found at www.ncbi.nlm.nih.gov/pubmed/?term=quilty+lc.

Adrian Raine (PhD, University of York, 1982) is the Richard Perry University Professor and director of the Jerry Lee Center of Criminology at the University of Pennsylvania. He is the author of *The Psychopathology of Crime* (1993, Academic Press), *Schizotypal Personality* (1995, Cambridge University Press), and most recently, *The Anatomy of Violence: The Biological Roots of Crime* (2013, Vintage).

Krystyn J. Ramdial, MS, is a doctoral student of industrial/organizational psychology at the University of Central Florida. Her major research interests include global selection, international use of emerging technology in the workplace, asynchronous and synchronous video interviewing, virtual and augmented reality use, and big data applications.

Kevin L. Rand is an associate professor of psychology at Indiana University–Purdue University Indianapolis. His research interests include personality processes involved in self-regulation and coping with stress. His recent work is on the differential influences of hope and optimism on self-regulation among patients with chronic or life-limiting illnesses.

John Rauthmann is currently professor of personality psychology and psychological assessment at the University of Lübeck. He received his PhD at the Humboldt-University

of Berlin and has worked as an assistant professor at Wake Forest University. His interests include, but are not limited to, personality structure, dynamics, and processes; psychological situations; and personality-situation transactions.

Peter J. Rentfrow (PhD, University of Texas at Austin, 2004) is a reader in the Department of Psychology at the University of Cambridge and a fellow of Fitzwilliam College. His research concerns person–environment interactions and focuses on the ways in which personality is expressed in everything from people's preferences for music to the places in which they live. Rentfrow's research on these topics has appeared in several of the most prestigious journals in psychology – including *PNAS, Nature Human Behavior*, *Journal of Personality*, *Journal of Personality and Social Psychology*, *Personality and Social Psychology Bulletin*, *Perspectives on Psychological Science*, and *Psychological Science*. He has published a number of articles on geographic variation in personality and edited *Geographical Psychology: Exploring the Interaction of Environment and Behavior*.

Ronald E. Riggio is the Henry R. Kravis Professor of Leadership and Organizational Psychology, and former director of the Kravis Leadership Institute at Claremont McKenna College. His research interests include leadership, organizational communication, social skills, and emotional and nonverbal communication. He is the author of multiple books and dozens of research articles.

Silvia Rizkallah, MA, received her bachelor's degree in psychology at Pennsylvania State University and is currently pursuing her PsyD at the University of Hartford. Her dissertation explores Iraqi adolescent refugees' experience of belonging in the school system in order to identify ways to improve mental health and areas for future change in the school system. Silvia's clinical interests include culturally sensitive therapeutic interventions, immigrant and minority mental health, identity, community engagement, issues pertaining to acculturation/acculturative stress, grief, and loss.

Laurie A. Roades is dean of the College of Health and Human Development at California State University, Fullerton. A clinical psychologist, her teaching and research interests lie in the areas of diversity and mental health and in allies across demographic groups.

Christopher R. Robert studied the biopsychosocial model while serving as a research assistance in the Center for Healthy Living and Longevity Lab and the Temperament Development Lab at the University of Texas at Arlington and is currently pursuing his PhD in School Psychology at the University of Florida and is engaged in two distinct lines of empirical inquiry: implementation of Multi-Tiered Systems of Support (MTSS) in schools and identification of learning disabilities (LD) using Response-to-Intervention (RtI).

Oscar Fernando Rojas Pérez is a fourth-year doctoral candidate in counseling psychology at the University of Missouri, where he has taught cultural diversity and difficult dialogues to undergraduate and graduate students. Oscar's research focus is on Latina/o immigrant well-being and coping, multicultural competencies, and development of culturally informed measures.

David Rollock (PhD, Yale University, 1989) is a professor and head of the Department of Psychological Sciences at Purdue University, and an affiliated faculty member of Purdue's

African American Studies and Research Center. He has served as director of Clinical Training for Purdue's Clinical Psychology Doctoral program, and director of the Purdue Psychology Treatment and Research Clinics. Dr. Rollock has been an officer of the Council of University Directors of Clinical Psychology (CUDCP), as well as the American Orthopsychiatric Association, and the American Psychological Association's Society for the Psychological Study of Culture, Ethnicity, and Race (Division 45). His research interests include minority mental health, especially emotional responses to interethnic contact, and intercultural adjustment.

Lia K. Rosenstein is a graduate student in clinical psychology at the Pennsylvania State University studying with Dr. Kenneth N. Levy in the Laboratory for Personality, Psychopathology, and Psychotherapy Research. She has been recognized by the North American Society for Study of Personality Disorders with a young investigator award for her work regarding borderline personality disorder.

David L. Rowland is senior research professor of psychology at Valparaiso University, Valparaiso, Indiana. He has published five books and over 200 papers on topics related to human sexuality, has served as editor of the *Annual Review of Sex Research*, and is currently on the editorial boards of six prominent journals. He is also co-founder and co-editor of the *Journal of Mind and Medical Sciences*.

Mark A. Runco is director of Creativity Research and Programming at Southern Oregon University (Ashland, OR), as well as editor-in-chief of the *Creativity Research Journal*. He approaches creativity from an interdisciplinary perspective and has published cognitive, psychometric, economic, historical, clinical, and genetic research on the topic. He is author of a popular textbook on creativity, published in 2004 and 2014 by Academic Press that is being revised for 2020, and co-editor of the *Encyclopedia of Creativity*.

Ana Isabel Sanz-Vergel is senior lecturer in work psychology at Norwich Business School, University of East Anglia. Her research interests are related to the field of work and organizational psychology, occupational health, and employee well-being, including topics such as daily recovery from job stress, work-family conflict, and crossover of work-related experiences. Her research has been published in journals such as *Journal of Vocational Behavior*, *Human Relations*, *Journal of Occupational and Organizational Psychology*, and *Journal of Occupational Health Psychology*. Email: a.sanz-vergel@uea.ac.uk.

Cindy Sayani is a graduate student at California State University, Northridge's Marriage and Family Therapy program. She is currently working as an MFT Trainee at the Center for Individual and Family Counseling in North Hollywood, California. Additionally, she is the editor of *The Networker,* a newsletter publication of CSUN's MFT program.

Tatsuya Sato (PhD, Tohoku University, 2002) is a professor at the College of Comprehensive Psychology and an executive director, Division of General Planning and Development, the Ritsumeikan. His research interests include history of psychology, cultural psychology and qualitative studies.

Nicola S. Schutte, PhD, is an associate professor of psychology at the University of New England, Australia. Her research interests lie in the area of positive psychology and include a focus on motivation, emotional intelligence, self-efficacy, and positive affect.

Arthur J. Schwartz is professor of leadership studies and founding director of the Oskin Leadership Institute (www.widener.edu/oskininstitute) at Widener University. Previously, he held the position of senior scholar at the United States Air Force Academy. Dr. Schwartz served for 14 years as a senior executive at the John Templeton Foundation where he helped to catalyze the field of positive psychology. He earned his doctorate in moral education from Harvard University. His current research focuses on the nature of moral courage. He edited and wrote the lead chapter in the Jossey-Bass volume *Developing Ethical Leaders* (2015).

Carolina P. Seigler (BA, sociology and poverty studies, Furman University, 2014) serves as the multi-faith coordinator at Elon University. Carolina's research interests include culture, stratification, and social movements. Select research topics include the social organizing efforts of low-income tenants in the Bronx, political mobilization of LGBTQ communities of faith in the Deep South, and perceptions of gender and statutory rape in Maun, Botswana. Carolina has presented her research findings at several conferences including those hosted by the Southern Sociological Association and the Southeastern Commission for the Study of Religion.

Matthew T. Seipel is a PhD student in counseling psychology at Iowa State University and a member of the Iowa Army National Guard. He also holds an MS in clinical mental health counseling from Marquette University. Matthew's research interests include vocational development and assessment, career counseling, military psychology, and mindfulness. He recently published articles examining the vocational well-being of non-tenure-track faculty and career decision-making in college students, and he was a contributing author for a textbook in abnormal psychology.

John J. Sosik is a professor of management and organization and professor-in-charge of the Master of Leadership Development program at the Pennsylvania State University, Great Valley School of Graduate Professional Studies. He received his PhD in Management from the State University of New York at Binghamton. His current research interests include transformational/charismatic leadership, character and leadership, e-leadership, mentoring relationships, and team dynamics.

Seth M. Spain is an assistant professor of Management at Concordia University. His PhD is from the University of Illinois. His research covers assessment of leadership potential, leader selection and development, job performance, and research methods.

Eric D. Splan is a postdoctoral researcher in the Department of Psychological and Brain Sciences at the University of Delaware. His research incorporates a broad range of behavioral and neural techniques in examining the social cognitive and neural mechanisms that underlie the experience and expression of modern discrimination.

Julie Sriken, MA, is a doctoral student in the Community Research and Action program at Peabody College, Vanderbilt University. She earned her MA in forensic psychology from John Jay College of Criminal Justice, CUNY and has worked as a counselor with nontraditionally admitted college students, most of whom were low-income women of color. Her experience also includes providing counseling and advocacy to survivors of intimate partner violence and sexual assault.

Steven Stone is an aspiring scholar, educator, and life-long student. Currently a doctoral student in the counseling psychology program at the University of Texas at Austin, his research interests and fieldwork are guided by the objective to liberate and empower marginalized groups and groups within oppressive systems. He mainly investigates Black or African Americans and White allies or White antiracists at the college level. A theme in much of his work is exploring psychosocial barriers, such as shame and belonging, that prevent individuals from achieving high quality relationships with themselves and with individuals of various racial backgrounds. Further, Steven is an advocate of the interpersonal process approach in therapy settings, and maintains self-care by practicing the martial art of jiu jitsu.

Karl W. Stukenberg is an associate professor in Xavier University's School of Psychology in Cincinnati, Ohio. He did his baccalaureate work at St. John's College in Santa Fe, NM, and graduated with his master's and PhD degrees from the Ohio State University. He did three years of postdoctoral training at the Menninger Clinic, which was then in Topeka Kansas. He is also a graduate of the Cincinnati Psychoanalytic Institute. His research has included publishing on aspects of the MMPI. In addition to teaching and doing research, he maintains a small private practice that includes doing personality assessments as well as psychoanalysis and psychodynamic psychotherapy.

James W. Sturges is professor of psychology at California State Polytechnic University, Pomona. His research interests include health promotion and behavior therapy. He is an author of articles in *Advances in Medical Psychotherapy, Behavior Therapy, Child & Family Behavior Therapy, Health Psychology, Journal of Pediatric Psychology, Journal of the American Academy of Child and Adolescent Psychiatry, Pediatrics,* and *Professional Psychology: Research and Practice*.

Aaron R. Tempel has a master's degree in clinical mental health counseling and is a licensed practicing clinician as a program therapist in the behavioral health unit within a partial hospitalization program. He has been a co-author on five published articles on issues related to human sexuality.

David Theil is an industrial organizational psychologist currently working as a talent selection specialist at a Fortune 500 company. In pursuit of a PhD in I-O psychology from Alliant International University, he is researching how personality interacts with various job factors to increase engagement in the workplace.

Tabatha Thibault has a master's in applied psychology and is a PhD candidate in industrial/organizational psychology at Saint Mary's University. Her research interests include the Dark Tetrad of personality, cyber deviant behaviors in the workplace, workplace dignity, and leadership.

Joshua Thompson is the primary investigator for the WWU Political Psychology Lab. He earned his bachelor of science in psychology at Washington State University and his master of science in experimental psychology at Western Washington University. He has presented work completed with Joseph E. Trimble and Jean Lau Chin based on their book, *Diversity and Leadership*, at the Association for Psychological Science conference.

Steven M. Tovian (Ph.D., Northwestern University, 1977) is a clinical professor of Psychiatry & Behavioral Sciences at the Feinberg School of Medicine at Northwestern University. He is board certified in clinical and clinical health psychology (ABPP – American Board of Professional Psychology). He is a Fellow in the American Psychological Association. He maintains an independent psychology practice outside of Chicago. He has published over 35 publications in refereed journals, book chapters, has co-authored two textbooks in clinical and health psychology. His graduate level teaching in clinical psychology includes health psychology in primary care medicine. His past work has included Chief of the Section of Psychology and Director of a Health Psychology program in an academic medical center. He has served as past Chair of the Commission for the Recognition of Specialties and Subspecialties in Professional Psychology (CRSSPP) in the American Psychological Association.

Alisia G.T.T. Tran is an assistant professor of counseling and counseling psychology in the College of Integrative Sciences and Arts at Arizona State University. Current areas of research include discrimination, ethnic-racial or cultural socialization, socioeconomic disparities, financial stress, and ethnic minority psychology. Recent publications include A. T. Tran (2015). "In these spaces: Perceived neighborhood quality as a protective factor against discrimination for Lesbian, Gay, and Bisexual (LGB) adults," *Psychology of Sexual Orientation and Gender Diversity, 2*(3), 345–352; A. T. Tran, A. T. and R. M. Lee (2014). "You speak English well! Asian Americans' reactions to an exceptionalizing stereotype," *Journal of Counseling Psychology, 61*, 484–490.

Joseph E. Trimble, PhD, is a distinguished university professor and professor of Psychology at Western Washington University and a President's Professor at the Center for Alaska Native Health Research at the University of Alaska. He has over 150 publications on multicultural topics in psychology including 21 books. He received numerous excellence in teaching and research awards for his work in the field of multicultural psychology, including: the Janet E. Helms Award; Distinguished Elder Award; the Henry Tomes Award; the International Lifetime Achievement Award; the 2013 Francis J. Bonner, MD Award from the Massachusetts General Hospital; and the 2013 Elizabeth Hurlock Beckman Award.

Dwight C. K. Tse (MA, Claremont Graduate University) is a PhD student and a project manager at the Quality of Life Research Center, Claremont Graduate University. His research interests include positive aging, autotelic personality, and volunteerism. His recent publication in the *Journal of Positive Psychology* investigates how group work and flow proneness mitigate the negative impact of overly high challenges on flow state.

Crystal Ukpong (MS, California State Polytechnic University, Pomona, 2017; BA, University of California, Irvine, 2014) is a recent graduate of Cal Poly Pomona's Masters in psychology, with an emphasis in marriage and family therapy. She recently completed a year-long traineeship at City of Chino Human Services working with children, teens, adults, couples, and families. Currently, she works as a behavior therapist providing home, school, and community-based services to children with autism. Her main interest is the relationship between race and the stigma of mental illness. In the future, she hopes to continue providing counseling services to young adults of color.

Edelyn Verona is director of Clinical Training in the Clinical Psychology program at the University of South Florida. She received her PhD in clinical psychology from Florida State University, and completed a clinical internship at Western Psychiatric Institute and Clinical, University of Pittsburgh Medical School. Her major research interests include biosocial factors involved in disinhibited behaviors, including externalizing psychopathology (e.g. antisocial personality, substance use), self-injury, psychopathic personality, and aggression/violence; gender differences in the development and maintenance of these syndromes; and the study of emotion and psychopathology more generally.

Chockalingam Viswesvaran (PhD, University of Iowa) is a professor of psychology at Florida International University. He has served on several editorial boards including those of *Journal of Applied Psychology, Personnel Psychology,* and *Journal of Organizational Behavior*. He was the associate editor of the *International Journal of Selection and Assessment* (2001–2006) and is currently serving as its editor. He is a fellow of SIOP, Divisions 14 (I/O) and 5 (Evaluation, Measurement, and Statistics) of the American Psychological Association, and the Association for Psychological Science (APS). He has published over 170 articles and 250 conference presentations besides six edited volumes.

Helen J. Wall, PhD, is a senior lecturer in psychology at the Edge Hill University, UK. As a personality and social psychologist, she is fascinated by what makes people "tick." Why do people behave as they do and why do we often change our behaviors in certain contexts? Her research specifically examines the role of Big Five personality traits in online self-presentation, susceptibility to persuasion, coping responses in workplace settings, and task sharing.

Kenneth T. Wang is an associate professor and the PhD program chair in clinical psychology at Fuller Theological Seminary. He received his PhD in counseling psychology from Penn State University. Prior to Fuller, Kenneth taught at the University of Missouri and worked as a staff psychologist at the University of Illinois. Kenneth's research focuses on psychological measurement, cross-cultural psychological adjustment, and perfectionism. He is a co-author of the textbook *Research Design in Counseling* 4th Edition.

Yoshiyuki Watanabe (PhD, Tokyo International University, 2009) is a professor of psychology at Obihiro University of Veterinary Medicine, Hokkaido, Japan. He serves as the sixth president of the Japanese Society of Personality Psychology (JSPP) since 2015. His research interests include theoretical issues of personality psychology and the history of personality psychology.

Kevin Wei is a doctoral student at the University of Chicago. His current research examines two areas: how moral convictions influence reactions to social norm violations, and the effects of procedural fairness on perceptions of the Chicago police and judicial system.

Daniel Winarick (PhD, Adelphi University, 2014) is an adjunct assistant professor of psychology at Queens College–CUNY and a clinical psychologist in private practice in New York City. He completed his doctoral dissertation research on schizoid personality

disorder (SZPD), with a focus on its construct validity and diagnostic distinction from avoidant personality disorder (AVPD) in the DSM-IV and DSM-V. He received his MA and PhD in clinical psychology from Adelphi University and his BA in psychology from Washington University in St. Louis. He has been appointed as assistant clinical professor of psychiatry at the Ichan School of Medicine at Mt. Sinai Hospital.

Arielle Wolinsky is a doctoral student at SUNY Albany. Her research focuses on the role of societal and cultural food attitudes on the development and maintenance of eating pathology.

Jake Womick received his BA in psychology at the University of Missouri and is currently pursuing his doctoral degree there. His research interests include well-being, meaning in life, especially as these relate to worldviews, values, and belief systems.

Keri Ka-Yee Wong (PhD, University of Cambridge, 2014) is an assistant professor of psychology at University of College London and former Betty Behrens Research Fellow at Clare Hall, University of Cambridge. Her research interests include early assessments of childhood paranoia and suspiciousness, antisocial and aggressive behaviors, schizophrenia-spectrum disorders, and cross-cultural comparative research. More information about her research can be found at keriwong.com.

Dustin Wood is a research fellow at the University of Alabama, and received his PhD from the University of Illinois. His research involves understanding how personality traits affect and are affected by their environments, and on how functional and process approaches can be integrated with trait models. He has also done considerable work on methodological and statistical issues related to personality assessment and modeling.

Haley M. Woznyj is an assistant professor of management at Longwood University. Her research interests include examining the attitudes that employees develop about their jobs and work organizations. A recent publication examines how supervisor job attitudes and workplace behaviors trickle down the organizational hierarchy to influence the job performance of their subordinates. She also has interests in workplace diversity, such as microaggressions that minorities experience at work and the implication for perceptions of fairness.

Jianxin Zhang (PhD, Chinese University of Hongkong, 1997) is a professor of psychology at the Institute of Psychology, Chinese Academy of Sciences (www.psych.ac.cn) and deputy president of the Chinese Association of Social Psychology. He, in cooperation with other scholars, standardized the MMPI-1 and MMPI-2 in Mainland China. Meanwhile, he co-developed the Cross-Cultural (Chinese) Personality Assessment Inventory (CPAI).

Mingjie Zhou (PhD, Institute of Psychology, Chinese Academy of Sciences, 2007) is an associate professor of psychology at the Institute of Psychology, Chinese Academy of Sciences (www.psych.ac.cn). Her research interests include basic theories and methods of personality, the indigenous personality of Chinese, and personality and interpersonal relationship.

My dad, Professor Bernardo "Bernie" Carducci, had a passion for life. He loved being a dad, celebrating Italian culture and community, and talking cigars with friends at the local smoke shop. My dad also loved psychology – teaching psychology, researching psychological phenomena, and raising awareness of the power and promise of an undergraduate psychology degree. He was an excellent teacher, scholar, and mentor who never lost sight of his roots as a first-generation college student, committing numerous hours and energy in support of student success. To those who knew my dad, it was no surprise. He was a personality psychologist. My dad had a BIG personality, evident in his bright ties, Hawaiian shirts, and zest for life. He was passionate about the study of personality and experienced tremendous joy in his life's work, the study of shyness. My dad was honored to be selected as editor of the latest volume of the *Wiley Encyclopedia of Personality and Individual Differences* and frequently shared with me his enthusiasm for the project. Although his unexpected passing prevented him from shepherding the book through the final stages of publication, I know he would be proud of the final product and wish to express his gratitude to all contributors and editors. I would like to extend a special thank you to Chris Nave for his willingness to assume editorial responsibilities of this volume upon my dad's passing.

Dad, I love and miss you very much. Congratulations on the publication of this volume!

Clinical Applications of Psychodynamic Theories of Personality

Karl W. Stukenberg

Xavier University

Personality Theory

Personality is determined by the most complex system in the known universe – the human mind, and its interactions with the world around it, a world filled with infinite cultural and individual variability. Each person has a unique mind and set of developmental experiences, creating a distinctive person with his or her own peculiar character. Psychodynamic theories of personality have brought considerable order to our understanding of the infinitely complex set of combinations of cognitive aptitudes and styles, life skills, styles of relating to others, emotional strengths and weaknesses and personal histories that we refer to as a person's personality. What could be simultaneously better known and more mysterious than the operation of our own minds? What is more familiar and stranger than the thing that we call our self? Even though the various psychoanalytic descriptive systems that have been developed are frequently incompatible with each other in one dimension or another, taken together, they form a means of both describing the potential that an individual has to develop – helping guide the therapist in facilitating growth – and the limits that a person may have in that development – helping the therapist work with the patient within the constraints that the person's personality organization, abilities, and motivations offer.

Since Freud's earliest writings, psychodynamic theories of personality have arisen and been applied in a clinical context. Freud was a research neurologist forced into clinical practice by the anti-Semitic politics of his time, and he turned to psychological explanations of neurological complaints when it was apparent that the causes of the symptoms were "neurotic"; meaning that there were psychological causes to what appeared on the surface to have been neurologically based disorders (Gay, 1968). By definition, neurotic symptoms were unwanted intrusions into a person's life, and therefore originally considered to be alien to the personality structure (Fenichel, 1945), but as Freud and others studied the character structures of their patients and also their own personality structures, it became apparent that the personality itself – the way a person characteristically approached

the world – was wrapped up in the symptoms that were to be addressed in treatment. Some personalities, or aspects of personality functioning, were considered to be disordered. For instance, a person's way of interacting with the world might be organized around warding off things that have germs or that are dirty or might be considered dirty, and this might lead the person to be emotionally remote so that they became chronically lonely and isolated – and this might register as what we would call depression. They would be "diagnosed," in addition to being depressed, not as having obsessive or compulsive symptoms, but as having an obsessive personality disorder. But it was also the case that the form that even more transitory symptoms take may be related to developmental issues and how they were resolved, as well as the use of characteristic defense mechanisms (Freud, 1905, 1923). For these reasons, the study of personality became ascendant in psychoanalytic theory and the treatment of the personality rather than directly treating symptoms became more and more the focus of psychoanalytic treatment.

Psychodynamic theories of personality have always been intended to be applied in a clinical setting. To this end, they are, at their best, dynamic descriptions of who the person is in the process of becoming rather than static descriptions of who the person is, and further they are descriptions of how best to join the person to help facilitate his or her ongoing developmental progress (McWilliams, 2011; Peebles, 2012). Psychodynamic theories of personality integrate information from a broad array of sources to help clinicians describe individuals' readiness for treatment based on structural strengths and weaknesses (e.g. reality testing, emotional regulation, verbal and spatial reasoning), developmental history including disruptions (e.g. trauma, conflicts, splits, and maladaptive behavior patterns), object relational maturity (whether the person is at a healthy, neurotic, borderline or psychotic level of functioning), and characteristic defenses (e.g. repression vs denial vs undoing) and all of this is understood in the context of the person's ability to make use of relationships to grow and develop. The goal of psychodynamic theories of personality is not just to discover the landmarks with respect to which people may be located (as occurs in a symptomatically based diagnostic system like the DSM or ICD), but to discover the addresses of the buildings in which people live (Holt, 1968) – something that requires the inclusion of the idiosyncratic personal information that is only relevant to this particular individual and how they and they alone engage with the world. Somewhat intermediary between these two points are generalized descriptions of how people function that allow this person to be compared to paradigmatic descriptions of others, and this is the basis of psychodynamic diagnostic systems.

Psychodynamic Psychodiagnostic Systems

Though psychoanalysis is the invention of Sigmund Freud, clinicians and researchers working from the psychodynamic perspective have been developing it for more than 100 years and the depiction of psychoanalysis that is in most college textbooks is terribly dated. Basic ideas that Freud initially articulated have been worked and reworked to more closely fit the observed experience of the patients that present at various clinics – and, indeed, the types of issues that people struggle with have developed and changed since the time of Freud – in part in response to the ways that psychoanalytic thinking altered our

understanding of ourselves and our symptoms (Gay, 1988). The following description of personality assessment from a psychodynamic perspective is one that is based in a contemporary understanding of personality – one that will continue to unfold and develop as we move forward in time.

The two editions of the *Psychodynamic Diagnostic Manual* (PDM Task Force, 2006; Lingiardi & McWilliams, 2017), include a description of the character functioning of a person as part of a comprehensive psychological diagnosis. The work on the PDM has been collaborative. Both the PDM and the current revised PDM task forces have been co-chaired by Nancy McWilliams whose text, *Psychoanalytic Diagnosis* (McWilliams, 2011) has gone through two editions. This work is an integrative diagnostic schema that relies heavily on a two-dimensional psychological space originally proposed by Kernberg (1975). The two dimensions are a system of sorting character styles based on characteristic ways of functioning – e.g. obsessive, hysteric, paranoid, etc. – and levels of character structure based on pathology – divided broadly into healthy, neurotic, borderline, and psychotic levels. The personality style (obsessive, hysteric, etc.) is not inherently pathological or problematic – it is descriptive of how a person goes about managing a variety of interpersonal and intrapsychic (psychologically internal) aspects of living. The level of character structure, on the other hand, is a continuum that includes assessment of the relative health of the personality. From this perspective, borderline level functioning is intended to be just that – literally occupying the borderline conceptual space between healthy and neurotic on the healthier end of the spectrum and psychotic on more disrupted end of the spectrum. Using this system, a person's personality or character can be roughly mapped by articulating their character style or type – e.g. obsessive – and the organizational level of their character structure – e.g. borderline. Thus, in the example above of the persona who is organized around a fear of germs and dirt, an individual can be located in the diagnostic space by characterizing them as having an obsessional character structure (they are afraid of dirt and germs is one part of this, though there are many other characteristics that coalesce to clarify that this is their style) organized at the borderline level (which would be the case if their concerns were, at times, unrealistic).

The character styles or types are clusters of characteristics that define the dominant ways a particular person addresses problems. There are a variety of familiar labels of these styles: hysteric or histrionic, obsessive-compulsive, dependent, avoidant, paranoid, schizoid, schizotypal and narcissistic, to name a few. Character style can be considered to be a description of a prototypical style – one that is based on confluences of characteristics that frequently co-exist. No person meets a characteristic style in all aspects and certainly not at all times. Using two or even three styles to characterize the central range of a person's functioning may more helpfully describe their style – especially when it is possible to say what kinds of situations evoke which aspects of their style – e.g. this person becomes more dependent in situations with less structure and direction, while they are more histrionic, meaning focused on connecting with people in a loving way, when they are more certain of what is expected of them. Ultimately, however, a true portrait of the individual will involve specific aspects of their personal developmental history, the variety of styles that they use to engage different types of problems, as well as characteristic conflicts and how those get played out in a variety of relationships and when confronted by various challenges.

McWilliams (2011) describes the various personality styles that she enumerates from the four classic psychoanalytic perspectives articulated by Pine (1990): drive, ego, object relational, and self-aspects of individual functioning. Below, using the examples of the histrionic (which has more traditionally been referred to as the hysteric style) and the obsessional styles, each of the four classical perspectives will be described. Choosing these two styles is based on the differences between them. They are, in some sense, caricatures of the female and male gender role stereotypes. People with the histrionic style are warm and energetic and they build their worlds around connecting with others. They can also become easily emotionally agitated but just as quickly return to more level-headed functioning when the source of distress is resolved. People with the obsessive or compulsive style on the other hand are experienced as being driven and emotionally remote. Though the style binds anxiety – it does it so effectively that there can be a machinelike experience of these individuals.

Drive perspective. From the drive perspective, individuals rely on dominant defensive strategies to manage the human drives (Freud originally posited a sexual drive and later added an aggressive drive. Psychologists have posited and sometimes demonstrated a host of other drives including curiosity as well as such things as affiliation and attachment). Defensive strategies redirect the energy of the drive toward various alternative ends, and these ends can both help and hinder the functioning of the person. So, for instance, the histrionic or hysteric style is characterized by repression, which is a particular kind of forgetting. This helps individuals with the histrionic style overlook aspects of another person that would make it hard to stay positively related to them, but it can interfere with retrieval of needed information, especially when under pressure. The obsessional style is characterized by exerting control. Afraid of being out of control, the obsessive has high expectations for themselves, which helps them achieve a great deal, but it is also a constant strain to be living up to what they imagine others expect of them.

Ego psychology perspective. Shapiro (1965), an early systematizer, working from within the ego psychological tradition, used cognitive ego styles to distinguish between types, noting, for instance, that the hysteric (or histrionic) style is characterized by global and broad cognitive processes. This allows the person to grasp the big picture and keeps them from getting mired in the details. The obsessive style, on the other hand, is characterized by great attention to detail. The obsessive tends to be highly organized and good at achieving objectives that have been clearly laid out to him or her, but may have more difficulty seeing the forest for the trees.

Object relations perspective. Object relations is a poorly chosen descriptor for understanding a person's interpersonal world. At one time, psychoanalytic theorists thought of people out there in the world almost exclusively as if they were objects in a particular person's mind. While that is true, people are also living and breathing and exist outside of each other's minds. In any case, a person with a histrionic style is primarily interested in relating to others in a loving fashion. They react positively toward others and expect that reaction in return. That said, they can be oddly uncomfortable with intimate relationships as if afraid that the other will discover that they are not valuable in a deep and sustaining way. A person with the obsessional style is interested maintaining hierarchical relational clarity – knowing who is reporting to whom, for instance, but they are also interested in providing for the other what is expected from them. The person with the obsessive style is

thus reliable, but can also be demanding and feel that others have not adequately lived up to what they have said they would, so that they can become rageful – which leaves them feeling out of control.

Self-Representation Perspective

Our self-concept is the way we make sense of who it is that we are. We believe ourselves to have central traits that describe us, and we tend to work to keep ourselves more or less consistent with those traits. Our self-concept serves as a means of organizing our experience of ourselves to ourselves – it is kind of our own assessment of our personality. The hysteric sees him or herself as small, defective and therefore orient themselves to others to get both direction and a sense of value – if you find me valuable, I may be better able to value myself, they may say in effect, but of course that can also lead to the fear noted above that if you really know me you won't find me of value. The obsessive, on the other hand, is deeply concerned with his or her moral standing and the ability to control his or her actions so that he or she does the right thing.

While each of us has home styles and primary ways of organizing our worlds, personality styles in actual people – not in the paradigmatic descriptions – include a complex interweaving of primary defensive strategies, cognitive styles, and other factors, some of which lie within the psychoanalytic range proper and others, e.g. a factor like intelligence, have been studied in psychology more broadly as well as from a psychodynamic perspective. The art of personality assessment in a clinical setting is to use the paradigmatic descriptions to guide the articulation of an idiosyncratic and unique integration (or failure to integrate) of a person's emotional, cognitive, interpersonal, and self-concept into the person that they are.

The categorical personality dimension does not have universal agreement among personality theorists. McWilliams, for instance, refers to fewer diagnostic categories in her book than are used in the PDM. The origins of the categories are based in clinical observation and new categories have emerged as new ways of conceptualizing human functioning develop – in the 1970s, for instance, there was considerable controversy about how to characterize narcissistic functioning, with theoreticians forming into camps who were supportive of Kohut's formulation of narcissism as a relatively benign personality deficit that interfered with completing various developmental tasks like advancing in education or a professional career because of interpersonal sensitivity versus Kernberg's characterization of narcissism as a destructive self-centeredness that had the potential to destroy relationships, harm other individuals, and wreak havoc in communities. Gabbard (1994) and others ultimately proposed that Kohut, who was working primarily with outpatients who were largely professionally and personally successful, and Kernberg, who was working primarily with inpatients who were referred for treatment after having caused significant damage within their families and sometimes their professional communities, were describing two very different clinical populations, with different etiologies and clinical presentations, but each having self-regard or self-esteem as a central psychological dynamic. The categorical system has spawned personality inventories, which will be discussed later in the assessment portion of this entry, and the inventories have lent empirical support to the

personality constructs as having reliability and discriminant validity – these are not just ways that clinicians stereotype, but they have scientific credibility.

Typically, categorical systems in the psychodynamic tradition have been defined by the maladaptive behaviors that cause individuals to come to the attention of clinicians. This can lead to harsh interpretations of the styles that hide the many healthy and creative problem-solving strategies that are integral to each style. McWilliams (2011) notes the following styles: psychopathic, narcissistic, schizoid, paranoid, depressive, masochistic, obsessive-compulsive, and hysterical. Each can have maladaptive features but they can also help a person thrive in various environments. The styles are clinically useful descriptions that hold together – that is, they are seen within people – they are not the result of statistical manipulation of self-report data in the way that the Big Five Personality Factors (McCrae and Costa, 1990) are, even though they also have scientific support. Some of the styles are associated with a wide range of psychological functioning – the obsessive-compulsive style, for instance, can be seen at the neurotic, borderline, and psychotic levels of organization – but some are more intrinsically pathological and are likely to be seen almost exclusively at the borderline to psychotic levels of organization – the paranoid style would be an example of this. That said, there are many individuals functioning primarily within the paranoid style who function well in society – especially if they find a niche that draws on the strengths of the style – for instance working for the Transportation Security Administration (TSA) might draw on some of the strengths of this style – an attention to detail and a basic level of mistrust – both of which might serve the ends of the organization, in this case identifying suspicious passengers, well.

The healthy – neurotic – borderline – psychotic dimension of the diagnosis has its roots in Kraepelin's (1913) system of distinguishing between levels of mental illness – based on creating a distinction between a psychologically determined illness (neurosis) and those with a presumed biological cause (psychosis). Later systems distinguished between neurotic – meaning symptomatic reactions to stressors – and character problems – meaning chronic maladaptive patterns of responding to the person's world. In the middle of the last century, a new and now overused intermediate term emerged; the borderline level of adaptation. Evolving out of early observations of hospitalized, nonpsychotic but deeply troubled and difficult to treat individuals (e.g. Frosch, 1964; Knight, 1953; Main, 1957), this conceptual region was more carefully charted by a growing number of people with a variety of methods of observation (Grinker, Werble & Drye, 1968; Kernberg, 1975, 1976; Masterson, 1976; and Stone, 1980, 1986). DSM-III-R (American Psychiatric Association, 1991) incorporated the term, but did so in a way that destroyed the dimensional aspect – Borderline was used as a categorical description – a description of what would basically be seen as a borderline level person with a hysteric or histrionic personality style from a psychodynamic perspective – and the term became reified in common language as a type rather than a range of functioning applicable to all types.

Despite the complications of relying on a term that has been hijacked for other purposes, psychodynamic psychodiagnosticians continue to value the ability to describe the level of psychological health that an individual displays along with a typological description. Healthy and neurotic functioning is used to describe the highest level of personality organization. These individuals have an integrated sense of identity (Erikson, 1968). Their reality testing is good, and while they are able to feel deeply and passionately about aspects of

their lives, they are not easily overwhelmed by feelings, nor are they likely to act impulsively on poorly understood feelings. The defenses that they use are higher order defenses – the hysteric's repression is such a defense. Sublimation, the ability to turn a base drive like sex, into a higher aim – whether that is painting or using a sexual interaction to express love for another person while also gratifying the drive, is another such defense. The issues that bring neurotic level people to treatment are quickly seen as ego alien – meaning as problems that need to be understood and addressed, and it is relatively easy to establish a treatment alliance with them. For instance, a man with a masochistic style who is organized at a neurotic level will be able to see relatively easily that his sense that another is doing harm to him is partly that he imagines that the other knows him well enough to know what will hurt him and he then uses this idea to feel more closely connected to that other person.

People with borderline-level personality organization are characterized by having an unstable sense of self, difficulty managing affects, and the use of more primitive psychological defenses (the hysteric organized at the borderline level would rely more heavily on denial – saying what happened didn't happen – than repression – not being able to remember clearly what happened) to manage the shifting, confusing, and sometimes chaotic internal worlds that they inhabit. As a means of describing a spectrum of functioning, there is a considerable difference between individuals functioning in the upper borderline level – who are more consistently perceived as being neurotic in their approach to the world, with dips in functioning that may be related to being in situations that are unstructured and/or emotionally demanding – when their functioning takes on more borderline characteristics, and those who are functioning in the lower borderline level who can be characterized as having more consistent challenges with a sense of personal integrity and whose reality testing may be problematic, again especially at times when they are in poorly structured and/or emotionally demanding situations. This should also help to clarify that psychodynamic personality diagnosis is less about a procrustean description of a two-dimensional character, and more about defining a central area of function – one that varies based on situational factors – including both environmental and psychological factors. If our person with a masochistic style described above were organized at the borderline level, he is more likely at the beginning of treatment to enact the masochistic relationship with a therapist and others in his life with little ability to reflect on this as something he has partially created, instead experiencing the other as visiting pain and suffering on him – and he would have little ability to reflect on the ways that this is reassuring to him. He might only be able to be puzzled about his continuing to engage in such a relationship after a considerable period of time in treatment and after other means of establishing a sense of connection with the therapist had been established. Once the patient became more secure in the relationship with the therapist, the two of them together might be able to talk about the ways that the patient felt hurt and damaged by what the therapist said – but also felt some gratification that the therapist knew him well enough to say things that would hit that close to home.

People with psychotic-level personality organization may not be floridly psychotic (meaning they may not hallucinate or talk nonsensically) – they may function in day-to-day life with apparent ability – though some of them have intermittent or even relatively continuous debilitating difficulties with reality testing and experience such symptoms as

hallucinations and delusions. What unites this group of individuals is a persistent sense of deeply felt existential concerns. Individuals in this range of functioning question their basic integrity as people – they lack a sense of continuity from moment to moment and/or from one part of their lives to the next. They fear the impact of their actions on others. They may be highly attuned to others – in part as a means of maintaining a sense of continuity and connection – something that is an essential struggle for them. Though the issues these individuals struggle with are much more severe and their symptoms can be more personally disruptive, as a group they are frequently easy to engage with – they are hanging on for dear life – instead of careening through life (more characteristic of the borderline level of functioning) – and tend to be more appreciative of people who are interested in connecting with them and helping them maintain contact with the world, though they also may not be able to sustain prolonged contact or to deal well with interpersonal conflict. Thus our masochistic individual might be quiet about the ways in which he feels injured in a close personal relationship in part because he fears that articulating this might threaten the relationship, and thus his personal integrity. Helping him to articulate this might require a deft ability to read between the lines of the relationship that emerges with him.

The clinical utility of psychodynamic theories of personality should be becoming apparent after this section. Psychological disturbances such as depression or anxiety or schizophrenia are not seen by the psychodynamic clinician as discrete phenomena, but rather as biologically, socially, and psychologically determined aspects of a person's functioning that emerge out of and are in constant dialogue with the personality style of the individual. The goal of psychodynamic treatment is frequently not symptom focused *per se*, but person focused. The goal is to treat people – and the personality is the context; it is the best available description of the person that a clinician is able to achieve as he or she works to help the person develop and cope with what is distressing to him or her and/or to the people around him or her. From this perspective, symptoms are integral aspects of the person who is being treated, not separate entities. As the person learns how to more maturely use their personality style – to move up the developmental axis – and becomes more confident that they can connect with others (including the therapist), they can find that their personality serves them better and that the symptoms are less prominent and interfere less in their functioning.

Personality Assessment

Psychodynamic assessment of personality has a long history that has contributed to psychodynamic theories of personality, but it also draws heavily on them. Rappaport, Gill, and Schafer (1968) published a manual describing a basic psychological test battery of a Wechsler Intelligence Scale, the Thematic Apperception Test (TAT), and the Rorschach Inkblot Procedure that has become a standard personality battery that people have used with various permutations (and from various theoretical orientations) since then. The original battery also included a word association test and other tests that are now less commonly included. Current batteries also frequently include self-report instruments (Bram & Peebles, 2014).

A basic premise of personality assessment from a psychodynamic perspective is that the instruments used to assess personality are a means for the clinician to have access to the person being assessed and that it is the clinician, not the instrument, which assesses personality. Personality instruments – whether "objective" or "projective" – are standardized means of observing a person's behaviors, and provide the clinician with data that then leads him or her to make inferences about both the personality category and the level of functioning of the individual being assessed. That said, some instruments are focused more heavily on one dimension or aspect than another.

Interview methods are likely the most common means of obtaining a personality diagnosis among practicing clinicians, and this is most likely done in unstructured interviews as part of an initial but also an ongoing assessment of patients. The Shedler-Westen Assessment Procedure (SWAP: Shedler & Westen, 2007) helps clinicians organize their observations of patients by having them do a Q-sort (deciding which items are most characteristic of the person) of 200 standard diagnostic statements which are then compared to national norms of patients in treatment being rated by their treaters. Kernberg (1984) has proposed a more structured interview, especially as a means of determining borderline level personality functioning. Stern, Caligor, Roose, and Clarkin (2004) have developed an empirically validated instrument, the Structured Interview for Personality Organization (STIPO) that provides a reliable measure of borderline level functioning.

Interview methods of assessment are central to the Case Formulation model of diagnosis, a model that traces, within psychodynamic traditions, back to the case studies of Janet, Breuer, Freud, Jung and Adler, that were formalized in the middle of the twentieth century (e.g. Menninger, 1952), and continue to be a central way that psychodynamic thinkers organize their approach to understanding people's clinical presentation (McWilliams, 1999). Other traditions also rely on the case formulation method (e.g. Eells, 1997; Ingram, 2006; Kuyken, Padesky, & Dudley, 2009). This method relies on creating a narrative out of various sources of information, including developmental history, presenting issues, stressors, relational history, and psychological resiliency into a narrative formulation, which is ultimately a complex hypothesis about the structural and dynamic organization of the person. This approach has been criticized for its overreliance on interview data, which is, like other forms of self-report, reliant on the reporter's ability to self-observe as well as being produced in an interaction where the reporter becomes a passive responder to the interviewer's activity. Another criticism has to do with the reliability of the narrative structure that is created (Peebles, 2012).

Self-report instruments are, in some ways a logical extension of the interview. Indeed, the originators of the Minnesota Multiphasic Personality Inventory (MMPI) intended for the instrument to serve as a more efficient means of collecting interview type information and originally thought that reading through the responses would be a means of interpreting the instrument. This quickly proved to be a task that was beyond the capacities of the clinician and the advantages of using statistical comparison to others taking the test became apparent. The Millon Clinical Multiaxial Inventory-III (MCMI-III; Millon, Davis, & Millon, 1997) is an example of a sophisticated symptom- and trait-based measure that, like the MMPI, can serve as a source of inferences about the functioning of the person – especially through the eyes of the patient themselves. That said, in constructing both instruments, researchers relied as crucial steps on the items' abilities to distinguish

between clinical groups *regardless of the content of the items* (more so for the MMPI than the MCMI), and this can help clinicians ascertain things about the person that they do not themselves already know (see Finn (2007) for evidence of this and how to use it interpretively), though the items do require a certain level of insight and comparative ability. A psychodynamic assessment of personality functioning should, by its very nature, be pointing the clinician and the person being assessed in the direction of *knowing more about those aspects of the person that they themselves don't yet know*, and this should be supported not just by theoretical relationships between something on the order of traits, but by intimate contact with the functioning of this particular person, and thus directly observing the person's behavior is an important component of most psychodynamic assessment (Meyer, 1997). Further, the assessment of a testing alliance – how it is that the assessor and the person being assessed work together – is an important predictor of a treatment alliance (Bram & Peebles, 2014).

Psychological testing batteries allow for observation of personality functioning in standard settings that are generally novel to the person being assessed. Bram and Peebles (2014) have written a text describing how to integrate material from various instruments – the Rappaport, Gil and Schafer battery form the core of their battery – that allows the clinician to observe the behavior of individuals in settings that have differing levels of structure and different demand characteristics – as well as opportunities to articulate narrative organization to ambiguous stimuli. Such approaches allow for the integration of nomothetic (comparison with groups of people) with idiographic (individually and idiosyncratically based) inferences about the functioning of individuals.

Psychological testing can afford norm referenced information about a person's cognition and learning style, reasoning, reality testing, emotional regulation, and relational capacities. These data can be invaluable in determining a course of treatment and can save tremendous time and effort that might otherwise be spent in pursuing treatments that do not fit with the capacities of the individual seeking help. That said, the criticism of psychological testing not meeting scientific standards for reliability and validity has led to efforts to improve the internal validity of tests (e.g. Exner, 2003; Meyer, Viglione, Mihura, Erard, & Erdberg, 2011), but these efforts can be a double-edged sword, with the potential for clinicians to cling to defensible and numerically supported conclusions at the expense of creatively engaging with individuals with the tests as aids in a process that is essentially humanistic while also being scientific.

For instance, the Rorschach Inkblot Procedure has long been a psychoanalytic tool used to make inferences based on what the patient "projects" onto the relatively ambiguous parts of the inkblot plates. Hermann Rorschach created his procedure in the early part of the twentieth century. He was working in a psychiatric hospital in a backwater part of Switzerland, and the Inkblot Procedure was his ticket out of the sticks. Unfortunately, he died suddenly and prematurely of appendicitis before that occurred, before he was able to exert control over how the Rorschach Procedure was used, and before he could let the world know that the stimuli he published were not inkblots!

To start with that last bit first, Rorschach was a fine watercolor artist. He was working with severely disturbed patients with diagnoses like schizophrenia, and he found that the inkblots that he initially used did not have enough structure for his patients to report seeing anything. So he copied them as pen and ink drawings with a watercolor wash. In the process of doing this, he *drew actual things to be seen* into the areas of the inkblot that had

originally been vague. Rorschach was primarily interested in being able to distinguish psychotic-level functioning folks from others, but when his instrument came to the United States, it was also used as a "projective" instrument, and the content of what people saw in the "inkblots" was used to make inferences about what was stirring their minds – what content made up their personality.

In the past 40 years, the Rorschach Inkblot Procedure has gone through two systematic iterations intended to improve its reliability and validity – to make it a better nomothetic (norm-based) instrument. The first iteration was Exner's Comprehensive System (Exner, 2003). Since Exner's death, an evaluation of the empirical basis of the Rorschach that led to the first Psychological Bulletin Article on it in decades (Mihura, Meyer, Dumitrascu, & Bombel, 2013) and also led to a subsequent revision of the Exner system, the Rorschach–Performance Assessment System (Meyer, Viglione, Mihura, Erard, & Edberg, 2011). What is apparent from this process is that Rorschach's original intent of the instrument, to assess psychotic level perceptual and thought processes, is the dominant strength of the instrument from the perspective of reliability and validity.

There are also variables on the Rorschach that are more "personality" related that have acceptable, but not as strong reliability and validity – such things as measures of dependency and extraversion/introversion, levels of introspection, and narcissism – and though the assessor is directed to look at possible projective content of particular responses, this level of analysis – one that can achieve great specificity – is not heralded as a reliable means of assessment. Despite it not being reliable – this assessor may assign different meaning from that assessor – it can, in skilled hands, inform the idiographic (individually based) understanding of the personality of this particular person. The ability to understand who this individual is gets compounded when idiographic information is used from multiple tests – where the skill of the clinician to integrate sometimes quite disparate information is at a very high level and requires knowledge of both the individual instruments *and* of how to integrate results from them. There are very few controlled studies that point to the reliability and validity of this most important (and powerful) clinical function.

Treatment Planning

Within the psychodynamic tradition, personality theory is intended to aid in treatment planning. Knowledge about the current state of the individual is used to predict both how to interact with that person and what kinds of treatment changes can be achieved. The irony is that a system that can be perceived to be static – who this person is – is being used to predict a developmental process – the unfolding of new ways of interacting, usually in the context of a therapeutic relationship. This can create a tension in that therapists can become overly reliant on a static description that can limit their vision of the person as a whole. This occurs frequently with the borderline personality diagnosis (from the DSM perspective) and is a criticism of using that diagnosis. People who receive the DSM borderline diagnosis can be shunned by treaters who assume that it is being used to describe people as difficult to treat – and the diagnosis is thus misused as an excuse to avoid engagement rather than to promote it. Perhaps more maliciously, simply holding in mind that a person is whatever categorical label one would assign limits the clinician's ability to engage

with that person as a whole human being who is necessarily more complex than any description, no matter how complete, can articulate.

As an illustration of the complexity of character, Stephen King was once asked in a radio interview whether the person who was driving the pickup truck that struck and disabled King as he was walking near his home – the driver was reaching over the seat to beat his dog and grab a beer when he struck King – was like a character from one of King's novels, and King replied that no living person could be a character in one of his novels, as any living person is infinitely more complex than any of his characters. And in that sense, any personality diagnosis, no matter how complex, reduces people to being characters or a set of characteristics. So it is incumbent on the clinician to use the diagnosis not as an end, but as a means to helping a person facilitate a process that helps the client come to better understand and use themselves as an instrument. One way of conceptualizing treatment, in fact, is that it is an extended diagnostic process the goal of which is for both therapist, but especially the patient to achieve a more broad-based understanding of their personality functioning. As this occurs, the patient should achieve greater autonomy from past constraints and, indeed, from some of the limiting factors identified in the initial evaluation so that they can direct their lives with greater freedom and come to know themselves more fully.

Despite the fact that all people are more complex than any diagnostic system can capture, describing the functioning of a particular personality system can help the treating clinician from two opposed positions. It can help the clinician know what to do – but also what NOT to do. First, it can help the clinician appreciate the configuration of the person and the types of interventions that will help the patient develop. Though this has a long history (see Horowitz, 1986 for instance), one of the most powerfully empirically supported examples of this is Blatt's distinction between anaclitic and introjective depressive experiences (Blatt, 2004). Anaclitic depression is characterized by exaggerated interpersonal concerns, and these include abandonment fears with accompanying loneliness, helplessness and feelings, of weakness. Introjective depression is focused around issues of self-esteem and questions about achievement. The introjective depressive experience includes a tendency toward a self-critical and self-evaluative attitude.

Blatt (1998) summarized the results of a series of studies about the differences between the therapeutic alliance of patients with anaclitic and introjective depressive styles noting that supportive psychotherapies lead to better outcomes with anaclitic depressives while "...patients preoccupied with issues of self-definition, self-control, and self-worth (patients with an 'introjective' form of psychopathology) demonstrate significantly greater therapeutic gain in long-term intensive psychotherapy and in psychoanalysis than do anaclitic patients" (p. 738). The interpersonal distance and autonomy promoting function of more interpretively based treatments, including psychoanalysis, are more useful to patients whose primary motivations involve self-improvement (the introjectives) while for those whose focus is on their sense of isolation and consequent wishes to connect, more supportive treatment addresses these concerns and the resulting stronger alliance appears to be related to more positive treatment outcome.

The treatment implications section of the test report is not always based on such firm empirical foundations as Blatt has afforded. More frequently, there is a mixture of the theoretical understanding of the personality style of the patient with the lived experience of the testing alliance that developed that leads to making recommendations. For instance, in an administration of the TAT with a very intelligent patient, the stories the patient told

hardly qualified as stories at all – instead they were primarily descriptions of the pictures with very little elaboration – even with querying for the prompted components of the story. The examiner, before presenting the fifth card, asked the patient if there was something about the testing situation that was interfering with his ability to engage in the testing process. A conversation followed in which the patient acknowledged that he felt coerced into the testing and the treatment as a whole. When the patient returned to the TAT, the story told in response to the next card was filled with rich details that were transparently related to the person's life and conflicts. This led the examiner to recommend that a treater use transference based interpretations (talking to the patient – as occurred in the testing – about what was happening between the treater and the patient at this particular moment) to help the patient articulate his experience, especially when he was feeling stuck in the treatment. This particular treatment recommendation is based on an immediate experience of a positive outcome based on a trial intervention.

Theoretical and empirical knowledge of the functioning of personality styles is a solid base from which to predict treatment interventions – including what NOT to do. Paranoid patients, for instance, frequently respond with angry and aggressive attacks when their delusional beliefs are confronted. This is because they rely on these beliefs to manage deep and frequently psychotic level fears. Having the pillars of what they experience as their reality testing removed is something that they react to with severe disorientation and try to fix as soon as possible. The person doing the assessment, in order to maintain the testing alliance, may assiduously avoid confronting delusional beliefs once they sense that they exist because of an understanding of the subsequent likely reactions. They will then predict such a reaction without having evoked it based on the rest of the information about the person. A treatment may then take place in which the person comes to relinquish their delusional beliefs slowly over time without having them ever overtly confronted as their developing ability to manage the underlying anxieties becomes stronger. In addition to saying what NOT to do, e.g. do not confront the delusion, the examiner may recommend that helping the paranoid patient address the underlying existential concerns, for instance, working to help the patient connect with people in their social world to reduce the need to feel that imagined others are watching them, and this, in turn, is based on integrating information about the person with theoretical knowledge about the condition.

Avoiding confronting a paranoid patient's delusions illustrates a common element of a treatment implications section of a test report. Though it is sometimes the case that the section is indicating what a therapist should do, more often than not it includes cautions about what to avoid in working with a particular patient. The assumption of the assessor should be that the treater is a generally competent therapist – and so treatment implications should not be generic, but particular to working with this individual patient. And then frequently the issue is one of warning a therapist to inhibit a usual and expectable therapeutic mode of functioning – for instance, to avoid too quickly correcting distortions with a paranoid patient – in addition to suggesting particular interventions – such as letting an introjectively depressed patient understand that treatment will very likely be effective, but will also likely take considerable time as they need to work toward feeling that they can rely on the therapeutic relationship, something that is really difficult for them to do.

A related issue, then, is the personality of the therapist. It is the responsibility of the treater to create a therapeutic environment for the patient. But therapists are no more infinitely flexible in their style of engagement than patients are. I highly respect a therapist

who works very well with individuals who present with severe and chronic alcohol and substance abuse on an inpatient unit. The consistent confrontation that is necessary in this work would be very difficult, perhaps impossible, for me to reliably provide, but the clinician I am describing thrives in this environment. On the other hand, she finds work with the client groups that are my bread and butter to be hard to manage as she experiences the emotional pull of the work to be so much less intense that she struggles to remain engaged.

Freud's only directive to his patients was to say what came into their minds – to freely associate. This turns out to be a much more complicated direction than it appears on the surface. In fact, being able to freely associate may be better understand as a therapeutic goal than a condition for treatment. Components of our personality – our defenses in particular – prevent us from freely associating. Defenses are intended to protect us from internal threats (thoughts that are forbidden or anxiety provoking) and external threats (interpersonal pressure). In addition to interfering with free association – resisting it and therefore treatment, our personalities help bind and direct our thoughts so that when they are flowing freely they are able to be goal directed and not simply random associations.

Contemporary clinical applications of psychodynamic personality theory are intended to help the patient and clinician work together to help the patient more fully inhabit themselves – to more fully exploit their personality style – one that is similar to others but ultimately unique and very much one's own – in order to live a more productive and happier life. The means to doing this is to provide, relatively early in the treatment process, a roadmap – a description of the elements of a person's interpersonal, cognitive and affective approach to the world – so that the therapist and patient can more quickly get to know each other and get to work on evaluating how best to develop the resources and manage the deficits that the individual brings with them to the moments in their lives.

In conclusion, psychodynamic theories of personality have a broad range of applications in clinical settings. Ultimately, psychodynamic therapists are trying to work with their patients to understand the patient – their personality – more fully. While the person's personality is, ultimately, unique, it is useful to get a sense of how it is that they relate to the world is similar to the ways that others do that. Psychodynamic psychotherapy has developed various diagnostic systems to classify personality. In this section, the current dominant system, one that is based on two-dimensional "mapping" of personality onto personality styles and onto how psychologically healthy the individual is was described. This was followed by descriptions of various techniques for assessing individuals, and then a final section that talked about how reports about people's psychological functioning are generated to help the patient and their therapist get to work on better understanding the functioning of the patient. The descriptions help alert practitioners to things they should do and, perhaps just as importantly, what they should not do in helping a particular individual come to better know and understand him or herself.

Clinical Applications of Behavioral Theory of Personality

James W. Sturges

California State Polytechnic University, Pomona

History of Learning Theory

Aristotle anticipated behavioral psychology by recognizing that people come to associate contiguous events. And like behaviorists, he valued observational methods more than mere reflection. Philosophers such as David Hume came to view association as *the* basic mental process, and empiricism became the core of the scientific method. These lines of thought and inquiry in Western philosophy served as context for Russian physiologist Ivan Pavlov's studies of classical, or respondent, conditioning in dogs. While studying digestive processes in dogs, he noticed that the sounds and other cues preceding delivery of food had begun to elicit salivation and secretion of digestive juices. The naturally potent stimulus of food had become associated with previously relatively neutral preceding cues. Going on to thoroughly investigate this phenomenon, he was able to understand conditioning under controlled conditions, assess its generalization to similar stimuli and the discrimination that occurs with regard to less similar stimuli. He also measured the strength of association during the extinction of, spontaneous recovery of, and repeated extinction of conditioning.

Pavlov's work in turn informed that of prominent psychologist John Watson. He and Rosalie Rayner famously induced a conditioned fear in infant Little Albert. Sounding a gong after the presentation of a white rat, Albert developed a conditioned fear of the rat and similar white furry objects. A believer in John Locke's tabula rasa, Watson (1924) famously wrote, "Give me a dozen healthy infants...and I'll take any one at random and train him to become...doctor, lawyer...thief," reflecting behaviorism's (and empiricism's) emphasis on environmental influences such as conditioning. In addition to being able to induce a phobia, Watson developed counterconditioning strategies using relaxation, and Joseph Wolpe went on to pioneer systematic desensitization, involving relaxation and graduated exposure to feared stimuli. Versions of exposure therapy became and continue to be the treatments of choice for anxiety, trauma, and obsessive-compulsive behavior.

Having rejected introspective mentalistic approaches, Watson did not explain behavior via innate personality traits. In fact, behaviorists and personality psychologists have debated the importance of situational specificity versus consistency of behavior across situations. Studies in the 1920s and 1930s had shown correlations less than .30 among various measures of children's behavior across situations, which was taken to indicate the greater importance of situational factors than internal ones. Walter Mischel (1968) further advanced this argument, but others responded with strong evidence of consistency within individuals over time across methods of measurement, aggregating data from multiple situations (Epstein, 1979). In addition to observed behavior, some self-report measures have been shown to be stable and to be useful in prediction. One such example is self-reported vocational interest, which has been shown to be stable over time and predictive of career choice. There is general consensus in psychology that there *are* stable factors not related to intellect (such as introversion-extraversion), which interact with environmental stimuli in specific situations (such as the presence of others). Behaviorists, however, are more likely to approach manifestations of these dispositions in an idiographic way – emphasizing the behaviors of the individual in response to the changing environmental conditions – and more as patterns of behavior than personality characteristics per se.

Nature-nurture views that exclude nature have been tempered within behaviorism, not only by evidence of cross-situational consistency, but by recognition of the preparedness of species for certain types of conditioning, such as the demonstration by Garcia, Kimeldorf, and Koelling (1955) of the more easily learned associations made by rats between nausea and taste than between nausea and visual cues. When radical behaviorists have given short shrift to biological preparedness they have faced tough criticism. For example, Skinner's account of language acquisition in his book *Verbal Behavior* (1957), although arguably an important contribution at a level of fine detail and an excellent explication of his theory, was famously and harshly critiqued by linguist Noam Chomsky (1959) for exclusion of innate factors.

As learning theory developed, it increasingly addressed the effects of reinforcement on the behavior of the individual, a sort of second-generation theory regarding instrumental behaviors operating on the environment, building on the work of the earlier theory of respondent conditioning. Edward Thorndike's research with cats learning to escape puzzle boxes to access food and water yielded his Law of Effect. Clark Hull (1935, 1951) developed drive reduction theory, which in its time was a very popular theory of motivation. Stimuli in the environment led to responses by the organism, and if those responses helped satisfy needs of the individual – drives – then the responses had been reinforced. The best-known and lasting contributions in this vein, however, were those of B. F. Skinner; the term Skinnerian is often used regarding operant conditioning. Skinner intensively studied and described schedules of reinforcement, shaping, maintenance, extinction, generalization, and discrimination. Skinner's radical behaviorism treats even thinking as behavior, albeit covert, subject to environmental contingencies and not free will.

Origins of Clinical Psychology

Two Pennsylvania-born students of German physician Wilhelm Wundt, founder of experimental psychology, Lightner Witmer and James McKeen Cattell, were key in the beginnings of clinical psychology. Witmer coined the term "clinical psychology" and in 1896

opened the first psychology clinic at the University of Pennsylvania to help children with academic and other problems. Although he would have been aware of Freud's work, Witmer's approach was more behavioral than psychoanalytic. Cattell was interested in the measurement of individual differences, and developed mental tests that helped launch the clinical practice of psychology. From the early 1900s to the 1940s, psychologists provided testing in medical, educational, civil service and military settings, and soon began providing treatments based on either psychoanalysis or learning theory.

Clinical psychologists now study, assess, treat, teach about, and provide consultation regarding psychological conditions. Only a minority of today's clinical psychologists are predominantly behavioral in orientation, yet behaviorism has been assimilated into clinical psychology, and is essential even to the contemporary zeitgeist: cognitive behavior therapy enhanced with experiential strategies such as mindfulness and acceptance.

Behavioral Conceptualizations of Personality

Neal Miller and his colleagues believed that Freud's anxiety paradigm was analogous to classically conditioned fears maintained via negative reinforcement (reduction of anxiety during avoidance), and that internal conflicts could indeed result in psychological difficulties. Dollard, Miller, Doob, Mowrer, and Sears (1939) examined the aggression-frustration hypothesis, in which blocked goal attainment increased aggression. Building on Hull's drive reduction theory, Dollard and Miller (1950) concluded that internal drives, such as hunger, along with external cues and reinforcers, yielded predictions of the range of possible behaviors that might be emitted in a given situation.

Hans Eysenck, who advocated an understanding of personality that included introversion-extraversion and neuroticism as basic dimensions, was one of the strong advocates for the use of behavior therapy as opposed to psychodynamic approaches, citing studies showing a complete lack of effectiveness of psychoanalysis (Eysenck, 1952).

Arthur Staats (1986) formulated paradigmatic or psychological behaviorism, advancing the idea that learned repertoires of behavior form an individual's personality, at a neural level, and then affect ongoing reactions to environmental stimuli. Children build on basic behavioral repertoires to develop more complex repertoires in sensory-motor, language-cognitive, and emotional-motivational domains. The repertoires act as personal causes of behavior. For more on this blend of behavioral and traditional understandings of personality, see Staats's 1996 book on psychological behaviorism, listed in Further Reading.

Applications of Behavioral Theories in Assessment

Behaviorism does not draw inferences about personality traits other than as defined by behavior patterns. True behaviorists use reliably measured and operationally defined observation systems. These rigorous approaches have resulted in very different types of assessment from the traditional ones within the field. Using traditional nomothetic approaches (studying groups), it is sufficient that paper and pencil measures, interpreted by respondents in unknown ways, correctly classifying responses (and by implication, respondents) as similar or dissimilar to those of known groups with particular characteristics. Items are included

in traditional measures based on this criterion-keying technique. In other cases, instead of focusing on criterion validity, test developers primarily seek content validity, by including items that are, theoretically, logically related to the core areas of an issue of interest.

Functional analyses of behavior prior to intervention seek to determine through careful observation which aspects of the environment may be triggering and maintaining difficulties. For example, tantrums in response to demands may provide escape opportunities. Behaviorists also use these idiographic forms of assessment during treatment, looking at very specific behaviors and changes in frequencies and intensities of those behaviors over time. Statistical methods are sometimes used to evaluate these changes within individuals, and are frequently employed by psychologists (including behaviorally oriented psychologists) to examine changes within a treated group compared to controls. However, behavior analysts particularly value assessment that clearly demonstrates changes in observations at the level of individuals. Charts are used to plot specific operationally defined behaviors of these individuals over time. In order to convincingly demonstrate behavior change following an intervention, the behavior analyst first determines that there is a stable or worsening rate of the behavior in question. If there is concern over a behavioral deficit (e.g. eye contact), then worsening is reflected by decreases. If the concern is regarding a behavioral excess (e.g. interrupting), then worsening would be a pattern of increase. The shift to the treatment phase should be data-driven. Observation indicates the point at which changes associated with treatment can be interpreted less ambiguously, because treatment is less likely to be occurring in the context of already ongoing improvement.

However, even when changes in behavior are associated with implementation of a treatment intervention, there can still be a "history" confound – something else in the environment may have changed at that moment. To evaluate that possibility, treatment may be removed in a reversal design. If this return to baseline is associated with a worsening in behavior, then this provides evidence that the intervention was the key ingredient in change. However, there are often clinical reasons not to go back to baseline conditions. Also, behavior may not change back even in a reversal of conditions, perhaps because contingencies in the natural environment are helping to maintain new behavior patterns. Therefore, other forms of evidence are needed. One possibility is to use other types of phase shifts that intersperse various treatments with each other for comparison. Notably, control can also be demonstrated by the use of multiple baseline designs across individuals, behaviors, or settings. An intervention might be implemented with one client first, or in only one setting, or with only one of several behaviors, and then once changes occur with the first of these, treatment is begun for the second individual, setting, or behavior, allowing a replication at a different point in time.

In all of these assessments, the rising and falling levels of the frequency of observed behaviors allow the behavior analyst (or anyone) to eyeball the chart and infer real changes. Just as in statistical analyses, there is still important clinical judgment involved in what constitutes important change from a practical point of view. Similarly, the choice of targets for intervention is an important clinical issue, which should take into account the wishes and consent or assent of clients and guardians, consideration of the relative importance and appropriateness of targeting the various behaviors, the opportunities for success, and so on.

Applications of Behavioral Theories in Treatment

Modification of behavior (as Thorndike had put it) involves interventions based on operant conditioning principles. In behavior modification's purest form, applied behavior analysis (ABA), functional assessments of behavior are conducted to detect environmental contingencies and the possible functions of behaviors. Treatment decisions are facilitated by ongoing observation, using single-subject or small-*n* designs.

Clinical child psychology would be at a loss without operant approaches, especially for externalizing and developmental disorders. Behavior modification has been widely used very effectively for children with attention-deficit/hyperactivity disorder (ADHD) and oppositional defiant disorder. Behavior management is clearly effective for ADHD, though more careful training of clinicians in relevant reliable assessment and adherence to treatment protocols is needed. Making heavy use of reinforcement principles to shape more appropriate and less defiant behavior of chronically oppositional children has a great deal of evidence for effectiveness as well, and the approach has become well-disseminated, accessible, and popular.

B. F. Skinner himself was particularly astute in advocating reinforcement-based techniques rather than punishment. He wrote the utopian novel *Walden Two* about a society based on reinforcement. Although punishment suppresses behavior, it may also lead to (a) negative emotional reactions, (b) changes in behavior only when the person implementing punishment is present (signaling the likelihood of punishment), (c) no new learning of what *to* do (only what not to do), (d) suppression of desirable behaviors, and (e) from a social learning theory perspective, copying the modeled punitive behaviors.

ABA is the treatment of choice for children on the autism spectrum. Treatments pioneered by Ivar Lovaas at UCLA for children with autism use ABA, including discrete trials with highly specific instructions and frequent rewards. The Lovaas method and behavior therapy in general have not been without controversy. Specific concerns have been raised about uses of punishment. Unpleasant stimuli are sometimes used to punish dangerous self-injurious behavior, for example. The Association for Advancement of Behavior Therapies (now the Association for Behavioral and Cognitive Therapies) helped guide development of regulations regarding ethical treatment of human research subjects and patients.

Aversive conditioning is also controversial. Imaginal aversive conditioning in attempts to change sexual orientation at the request of patients was strongly criticized as both ineffective and inappropriate, and is now proscribed. On the other hand, aversive conditioning in other contexts such as smoking cessation or alcohol use disorder has generally been accepted, though not generally considered to be very effective except in highly motivated patients.

ABA has been widely shown to effect socially desirable change across a variety of behaviors and situations, many of which are documented in the *Journal of Applied Behavior Analysis*. As just one example, in education, behavioral training has shaped skills using immediate feedback and rewards to help students attain mastery of material.

Methods to promote generalization of behavior change across situations and maintenance of change over time were described in a highly cited article by Stokes and Baer (1977): Train with a variety of situational examples, include aspects of eventual settings, train in different

ways, address situations that do not show generalization, provide opportunities for existing contingencies in the environment to be helpful, use unpredictable reinforcement, give learners a language to understand the changes they need to make.

In clinical settings, behavior therapy has flourished in the treatment of a wide range of disorders. Even following the latter twentieth-century shift toward social learning theory (Mischel, 1973) and cognitive behaviorism, basic behavioral principles have continued to be integral in clinical applications. For example, although cognitive therapy is the principal psychological intervention for the most prevalent serious mental health difficulty, depression, behavioral activation (teaching how to appropriately schedule beneficial pleasant activities) has been found equally effective to cognitive approaches, and more effective than insight-oriented or client-centered approaches.

Although most behavioral interventions for psychological disorders are fairly brief, this is not always the case. Some behavioral deficits or excesses may require ongoing contingency management, and some psychological disorders benefit from longer-term treatment. Dialectical behavior therapy, a treatment for patients with emotion dysregulation, instability in relationships, and self-image problems, is the longest-running behavior therapy. It may extend over a several-year period. With caring provision of structure and training in a wide variety of skills, patients learn more adaptive ways of handling the distress associated with their internal and interpersonal difficulties. Social skills, assertiveness, and anger management techniques have also met with great success in a variety of populations and situations.

Behavioral medicine, which applies behavioral principles in the medical arena, has been beneficial in work with pain, stress and coping, adjustment to chronic illness, skills building, health-related lifestyle change, adherence to medical regimen, enuresis, encopresis, prevention of HIV, pill-swallowing phobias, diabetes management.

Operant approaches have been widely recognized as important in pain management. Pain behaviors and medication seeking often come under environmental control, further reducing levels of functioning and becoming associated with greater patient distress. Adaptive behaviors should be reinforced, but not maladaptive ones. Relatedly, putting medications on scheduled dosing rather than being given on as-needed basis has been shown to reduce escalation of pain behaviors between doses.

Behavioral techniques for dealing with stress and anxiety have included strategies such as progressive muscle relaxation, deep breathing, yoga, exercise, and exposure therapy.

Promoting adherence to medical regimen and healthy lifestyle has involved rearranging the environment to promote change: Reducing contact with discriminative stimuli for unhealthy behaviors (people, places, and things associated with poor choices), getting other people involved to help manage contingencies, and replacing old habits with new ones. Many other behavioral approaches have been used in various health-related conditions: Shaping procedures to train pill swallowing, role-play and rehearsal to inoculate against smoking initiation, cue-exposure in preventing substance abuse relapse, making painful procedures more predictable and thus less anxiety provoking. Painful medical procedures have been studied extensively by behavioral psychologists, especially for children. The behavior of others present during medical procedures turned out to be important in child coping and distress, and the children themselves have been successfully taught helpful skills.

Future Directions

The future will likely bring increasingly greater integration of behavioral clinical psychology into health care. Other health-care providers and third-party payers will continue to value coherent and applicable treatments that work. The parity of mental health conditions with other health problems is increasingly accepted. It is widely recognized that provision of mental health services reduces overreliance on other health services and that behavioral strategies are the key ingredient in prevention of health problems. Behavior therapy will continue to thrive in the current climate of measurable outcomes and cost-effective interventions.

Psychoanalysis gave us the talking cure. Humanistic psychology made empathy, warmth, and genuineness the *sine qua non* of psychotherapy. Behaviorism provided empirically developed theories of change and demonstrably effective applications. Evidence-based treatments that work are often drawn from the behavioral reservoir using precise and quantifiable outcome measures. Laws of behavior from learning theory inform our knowledge of our conditioned responses, how our behavior is affected by the environment, and how to effect behavior change. A failure to understand these principles is a failure to understand ourselves.

Clinical Applications of Humanistic Theory of Personality

Stan Charnofsky and Cindy Sayani

California State University, Northridge

Humanism: The Third Force in Psychology

In 1956, Humanistic psychologist Carl Rogers and behaviorist B. F. Skinner engaged in a passionate debate (Rogers, 1989). This debate focused acutely on what precisely it means to be a human being. While Rogers emphasizes *inner* life, including will, choice, freedom, feelings, growth, courage, and self-actualization, Skinner emphasizes *outer life,* observable behavior, reinforcement modes, and issues of shaping and control. Skinner argued that the "personality" and inner life are fictions that are often used to account for reality, and that reality is primarily external. People, Skinner noted, are confused that their behavior is based on their "will" or "innerness" while in fact the cause of behavior is a history of external reinforcement from the past, in which actions have been met by consequences that have shaped them. Rogers, on the other hand, expressed dismay at this view of human life, and noted that his reality was filled with individuals with rich inner lives. He stated that feelings are vital and one must recognize and attempt to understand and accept them through Humanistic therapy. He notes that we have an inner compass that guides our activities. His big criticism of Skinner is that his is a world with no freedom or meaning, and that people are more like robots and are only shaped by external reinforcers. In Skinner's view, therefore, there is no room for creative behavior, which would deny the inner brilliance of a Beethoven, a Mozart, or a Picasso. For Skinner there is no possibility of a human being who is not *shaped*. One must assume in this view that the brilliant artists and performers were conditioned from birth on to express their genius. This vast contradiction in the two arguments points to a radical difference in what a human being is.

Further illustrating this contrast between humanistic therapy and behavioral therapy, Skinner and Rogers also engaged in a discussion on the purposes of psychology (Rogers, 1989). Skinner noted that the purpose was the prediction and control of human behavior. Rogers' response was that in his experience, the healthiest human behavior was spontaneous and not predictable. In humanism, there is the acceptance that we are not solely products of rewards and conditioning, but that we are creators as well. Some acts originate with

us, in the moment, and are not found elsewhere. Without that in-the-moment creativity, we would have no Einstein or Hemingway, or Tchaikovsky.

To add to Rogers' humanistic insights, it is valuable to understand that his view of the human condition is very positive. His argument is that when the ideal self and the actual image of a person are congruent, then that person is on balance and on the path toward Maslow's notion of self-actualization. Different from the deterministic emphasis in behaviorism and in Freudian Psychoanalysis, Rogers' humanistic outlook is imbedded in the belief that human beings have the capacity to grow toward their own highest state. We are, the humanists insist, packaged right at birth, and are turned away from our good health by wounds that occur from a myriad of sources. Different from the Freudian emphasis that sexual issues are the prime promoters of neuroses, the humanistic therapist assumes the position that it is a difficult world in which to grow up, and to get hurt is often inevitable. As the Gestalt therapists often note, the key to change in one's outlook is awareness – therefore, the therapist's task is to assist the client to become aware.

Existence and Essence

A primary question asked by the existential-humanistic psychologist might be what comes first, existence or essence. This question references two points of view, that of the classical philosopher versus that of the existential philosopher. The classical philosopher will say essence precedes existence, which tends to lend credence to a creator giving life to organisms. *I think, therefore I am*, is the classical line (Descartes, 1637, pp. 19–20). *I am, therefore I think*, is the existential retort. When the classicist insists that *I think, therefore I am*, comes first, the existentialist may ask, "What is the first word in your sentence? 'I' has to be there before you can think." An existential position might be that we are "thrown" into existence (perhaps by a deity, perhaps not), and from the moment we are born must make the decision to breathe and live, or not breathe, and die. From that instant on, existentialists say, though certainly at a cognitively naïve level in the beginning, we are responsible for choices in our lives. The humanistic psychologist embraces the existential credo that we have free will and are our own life designers. Another way to say it is that we are brought (or thrown) into existence without a predestined life prescription, and are steadfastly – though sometimes unevenly – devoted to refining our essence. Therapy, in that existential sense, is a process of helping to open one up to his or her natural potential.

Relationship

Humanistic therapists tell the apprentice that therapy is about the relationship, no techniques, no manipulation, no advice giving, and by encouraging *choice*, no behavior modifying (Glasser, 1998). Often the questions are asked, "But what do you do? How does it work? What do you say?" Historically, the humanistic-existential therapist has evaded such questions with responses such as: "You create a climate where the client feels safe. You prize the client. The client has a natural, organismic drive toward health. We are all self-correcting organisms. The relationship you create is what heals."

Since steps are not specifically spelled out, it is possible that the budding humanistic therapist may become frustrated and turn to more prescriptive approaches such as behaviorism or psychoanalysis. Humanistic professionals, however, see compelling reasons to select the humanistic-existential approach either for a client or a new student therapist.

Maslow (1954), considered a leading architect of humanistic psychology, proposed a hierarchy of motivational needs, from the lower-order physiological needs (food, shelter, and safety), to the psychological needs (love, belongingness, and self-esteem), to the higher-order growth needs (aesthetic needs and needs to know), and finally, what Maslow labeled self-actualizing needs. In Maslow's chart, one may only address the higher-order needs if the lower-order ones are at least minimally satisfied. What appeals to clients seeking therapeutic help is the nonjudgmental aspect of Maslow's self-actualization, and its egalitarian application in Rogers' person-centered approach. It is not a competition, but a striving toward one's own highest potential. Some people in the psychology field consider Viennese psychiatrist Alfred Adler to represent the origins of the Humanistic approach, though Adler was gone long before the Old Saybrook founding meeting of the Association for Humanistic Psychology. In contrast to Freud, Adler was considered a social psychologist that emphasized cultural involvement, family influences, birth order, and the rise from an inferiority position (born toothless, hairless, unable to speak, etc.) toward a life-goal of superiority. Adler also may have been the first truly feminist psychologist, who was quoted in *The New York Times* as far back as 1935 saying that women's being inferior to men was a colossal myth (Adler, 1935).

Why Humanistic Therapy?

In his newer books about Choice Theory, William Glasser (1938) applauds the twentieth century as one of technological triumph, but notes that it comes at the expense of social communion. Our children now can reach out to the cosmos, yet not know how to nurture each other. To Glasser (1938), a prime culprit in this disparity is "stimulus-response." He declares that no one truly responds to a stimulus; one responds out of personal choice, e.g. going through a stop sign at three in the morning, or deciding not to answer a ringing phone. Glasser insists that all behavior is chosen; therefore, one is responsible for all s/he does. Humanism as a psychology approach can only flourish in a culture that values Humanism as a philosophy. Many humanistic practitioners follow the existential writings of philosopher Jean-Paul Sartre and others in focusing on the importance of *being* and the meaning of life. This is a reaction to quick-fix therapies that endeavor to solve a single immediate problem and not go deeper. As Carl Rogers has expressed, a plant is neither good nor bad but rather grows to its healthy maturity given a nurturing environment of water, sun, and soil. In the same way, humans are not good or bad, and in a nurturing climate will strive toward their own organismic health (Rogers, 1987).

Humanistic practitioners believe their way may lead a troubled culture to find its healthy path. More than any other, humanistic-existential therapy *models* democracy, imposes upon the client least of all. Freedom to choose is maximized. Each person's human potential is validated. Many other therapeutic approaches advocate intake interviews and the

collection of historical data. The sessions themselves include note taking and a myriad of questions. From the humanistic perspective, the therapist wishes to encounter the client freshly, in the moment, with no pre-session bias, two people meeting and learning from each other. The therapist does not think of self as the expert one and the client as the poor, suffering, and by implication, *less than,* needy one. It has been expressed that the therapist may be an expert in the field of psychology but the client is the expert on him/her self. If one takes notes during a therapy hour, it means possibly missing bodily and facial expressions that provide valuable insight. The humanistic therapist tries to devote full attention to the client. As well, there is a sense of responsibility to the wider culture in the humanistic-existential approach. As far back as 1973, Walt Anderson, a member of AHP, wrote an incisive book, *Politics and the New Humanism,* wherein he writes that we do not do therapy in a vacuum but within a societal and political climate. He labels the old deterministic approaches as politically conservative, and humanistic psychology as promoting societal openness (Anderson, 1970).

Organizations and Publications

Paradoxically, the relationship and societal aspects of humanistic psychology, which encourage clients to grow and change along their own paths, caught on so well that other more prescriptive theoretical approaches not only borrowed, but also absorbed them whole cloth. The result is that the organization founded in the 1964 Old Saybrook meeting, The Association for Humanistic Psychology (AHP), has seen its membership dip from several thousand to less than a thousand. Though there is still a national board, AHP no longer has a headquarters (most recently in the Northern California area) but functions almost entirely online. Some see this as disturbing, yet others note that it is a grand achievement that the traditionally prescriptive cognitive, behavioral, postmodern, and even self psychology – a more modern version of psychoanalysis – have now adopted the principle that therapists create a caring, nonjudgmental connection with clients. Aside from AHP, the humanistic focus is the primary concern of Division 32 of the giant American Psychological Association (APA), so that there is clearly recognition of its ongoing value.

Abraham Maslow and Anthony Sutich founded the national *Journal of Humanistic Psychology* in 1958, and its first edition appeared in 1961. It remains the official journal of AHP as well as Saybrook Graduate School in California. It continues to be published as a quarterly research magazine by Sage Publications, located close to Los Angeles. Now retired, Dr. Tom Greening was the editor for over 35 years; he was succeeded by the current editor Dr. Kirk J. Schneider.

In California, on the campus of California State University, Northridge, several national humanistic conferences were presented in recent years. National conferences were routine 30 years in the past, rotating from East Coast to West Coast each year. Locations such as Boston, San Diego, Washington DC, and San Francisco were the sites of meetings where each time a few thousand people attended, with leaders in the field as presenters. However, the cost of putting on these conferences – which often took place in luxury hotels – became prohibitive. One in Tacoma, Washington, in fact, lost some 30,000 dollars. As a result, the

meetings were put on hold for a few years. In 2004, a conference organized and held in Northridge, CA, entitled, *Opening Hearts: Seeking Peace in A Chaotic World*, was a success in revitalizing the Association for Humanistic Psychology. Among the presenters were: Maureen O'Hara, President of Saybrook Graduate University; Natalie Rogers (Carl Rogers' daughter) who presented on Creative Arts For Peace; Carolyn Costin, founder of Monte Nido, a world-class residential facility for eating disorders; Jordan Paul, author of the best-selling novel *Do I Have To Give Up Me To Be Loved By You?*; Cuf Ferguson, president of AHP; Tom Greening, editor of the *Journal of Humanistic Psychology* for 35 years; Gerald Corey, author of 14 textbooks in the psychology field; and William Glasser, MD, author, and founder of Reality Therapy and Choice Theory. This conference was one of three offered at a university, which saved the Association for Humanistic Psychology some heavy expenses. Visitors from all over the country were housed in student dormitories, which again saved money. One salutary aspect of the humanistic tradition is that there have always been a number of volunteers who have contributed to the workshops' successes. With the new developments in technology, online correspondence is replacing some of the live conferences. Consequently, AHP's printed newsletter, *The Perspective*, is no longer printed out in hard copy. There is recently a renewed thrust to recruit more young people, mostly college psychology or family therapy students, into the fold.

A Clinical Operational Guide

Here are several practical points in applying a humanistic outlook in the therapeutic process:

Be Present: Client and Therapist

University of Southern California psychologist William Ofman called it H-E, humanistic existentialism, where he cites the personal encounter between him and his client as a microcosm of life (Ofman, 1976). *Be present* is the essence of his approach. What s/he is willing to do in the therapeutic encounter will be an appliqué on that client's life. Risks taken with the therapist are practice moments for risks to be taken with others. Equally important is an awareness that the healthiest personalities have the capacity to live fully in the present (Perls, 1969). Frederick (Fritz) Perls (1969) wrote that most present moments are not anxious and his phrase "Anxiety is anytime you leave the present" seems to be proven again and again in therapy work. Humanism tries to correct the saying: Happiness is something we remember, not something we experience (Levant, 1968). The psychologist may often ask the client, "What are you aware of right in this moment?" Perhaps the client may respond: "I'm aware that tomorrow I have to take an exam," to which the therapist may answer, "Not tomorrow; what are you aware of right here, right now?" The client may then realize, and say, "I hear cars going by outside, there is a plane going over, your carpet is red, my fingers are tingling…" The key to vibrant living is to be aware of one's present moment, and in the several minutes focusing in this exercise, the client cannot be anxious about the past or the future.

Act Responsibly: Client and Therapist

The humanistic-existential view is that there is absolutely no escape from personal responsibility. This is not laid out as a fiat or a warning; however, the therapist models responsibility – to be honest, and to confront the client in a nonthreatening yet unambiguous way. Responsibility is the antithesis of blame or fault. In a humanistic perspective, there ought not be BLAME, SHAME, FAULT, or GUILT (Charnofsky, 1997). The cat is blamed for spilling the milk. It's a shame when a game is lost. Guilt is for criminals caught in the act, and a fault is a jagged line in the crust of the earth. For humans, we are RESPONSIBLE for our life decisions, and for getting on with things despite disappointments and setbacks. It is often the task of the therapist to consult with a family where a teenager is acting out, the parents finding fault with their disobedient child. Parents may say, "Look what s/he is doing to us, and the humanistic reply may be: 'For them, not to you'." The teen is struggling for identity and that sometimes involves pushing away those who have been identifying him or her in the past. A humanistic way of addressing the adolescent about this is to remind him or her that the freedom being sought is partnered with an awesome twin: responsibility.

Listen: Client and Therapist

One vital point in the humanistic agenda is the manner in which the therapist presents him/herself to the client. It is as a profound listener rather than an interpreter or an analyst. Rogers never analyzed and regularly would work diligently to clarify what the client presented. With young students, there is too often the mindset that one must interpret the client's words and jump in to explain what is right or wrong about them. It becomes more of an imperative to sit across from clients with an attitude of "how does this person see her current life issues, and how can I clarify them for her." This also emphasizes a lack of judgment on the therapist's part – no good or bad scenario. It is often noted that there are no bad clients; clients simply present what they present, and the therapist must take it in as their way of seeing the world.

Provide a Stimulating Environment

Freud and followers stressed a barren external environment to allow a patient to go deep within, to encourage what came to be known as transference uncontaminated by extraneous stimuli. Carl Rogers once noted that to use the word *transference*, so vital in the Freudian repertoire, may completely miss the uniqueness of the I-Thou (borrowed from Jewish philosopher Martin Buber) encounter with this particular client (Rogers, 1987). In a humanistic sense, everything is part of life: color, music, and noise, including unavoidable interruptions. However, even in a pristine environment, the clients are treasure-chests of their own stimuli. They carry with them a bonanza of historical highlights and their presumed consequences. A quote sometimes seen on a poster that catches the essence of a stirring internal milieu comes from philosopher Albert Camus: *"In the midst of winter I finally learned that there was in me an invincible summer"* (6 January 1960).

Provide a Safe Environment

In Humanistic applications, the client's feelings of safety are paramount. Often, a client is in therapy because of a fear of one kind or another: loss of a person, health, freedom, and/or love. Fear may be the culprit in depression as well as anxiety, and certainly plays a role in what has come to be known as bipolar disorder. The therapist may suggest that clients visualize a familiar safe place and go there in their minds, or in group therapy offer a moment of "centering" where members breathe deeply and clear their thoughts. Some may call this *mindfulness*, the current popular phrase, though it is rather the same thing as Perls stressing awareness. As in all the Humanistic activity, participation is voluntary, not demanded. It defeats the notion of safety if the therapist takes the role of controller or pre-scriber. As Rogers (1987) has reminded: we must prize our clients as unique and capable individuals. Or, as Pablo Casals (1970), the brilliant cellist, once wrote (which fits nicely with the Humanistic view) we are all one-of-a-kind-marvels.

Look for Client Code Words

In humanistic therapy, there is respect for the client's ability to come up with key words or phrases that will help to assuage troubling patterns. One verbal report passed on by a prac-ticing therapist was about a client whose father had died of a heart attack at the age of 38. This client was constantly fretting about his health, managed to sabotage outings, and was often out of breath and choking. He told his therapist of a concert he and his wife were attending when he began to have his typical anxiety symptoms. His wife offered to turn around and go home (some might call her an enabler), but the man swallowed laboriously and told her, "Screw it! If I die, I die. Let's go in." The therapist used this person's own phrase, and each time he would begin to tumble to a low place, would remind him, "Remember, screw it!" It does little good for the therapist to invent the words that have meaning for the client. It is the client's task to use his or her own resources to move toward a natural state of better health.

Respect a Developmental Base

One need not presume that because existential theory and Gestalt therapy promote a present-time focus, a developmental history is to be ignored. Our history is what got us to where we are. However, as Alan Wheelis (1973), in *How People Change*, tells us, we are not trapped in our history; awareness cuts the chains that bind us to causative issues. It is vital to recognize that many therapies require expressed goals in a therapeutic encounter. In humanism, there may be perhaps only one specific goal for clients: *their enhanced aware-ness*. Harvey Jackins, in his book *The Human Side of Human Beings*, points out that we are all born zestful for life, spontaneous in demeanor, and supremely intelligent potentially (presuming no forebrain damage). What goes wrong with many of us can be expressed in three little words: *we get hurt*. Our zest shuts down, our spontaneity is blocked, and our intelligence is compromised by patterned, protective reactions to old hurts (Jackins, 1977). Jackins (1977) claims that healing from old hurts occurs through discharge of painful ten-sions, naturally done by children (crying when hurt, stomping and raging when angry,

shivering and shaking when frightened) but culturally suppressed by adults. Yes, we are influenced by our developmental histories, but we can recover our zest, spontaneity, and intelligence through awareness and emotional discharge, which permits us to reevaluate old hurts.

Realize That Affective Discharge May Precede Cognitive Restructuring

Cognitive therapists argue that a changed way of thinking will drag along with it emotional detritus (Beck, 1976). Humanistic therapists might argue the opposite: that our thoughts are scrambled because of affective dissonance, and one can only think straight after blocking emotions are discharged. Jackins (1977) notes instance after instance of such a sequential order, where someone has wept, raged, trembled, and sweated, and then says, in a calm voice, "Now I know what I have to do."

From a more humanistic perspective, the point is that until old, hurt patterns are flushed out through emotional discharge, full intelligent decision-making may not be available, though the therapist will rarely take an immutable stance on this. In a non-absolutistic sense, the Humanist will be open to cognitive change *sometimes* preceding emotional movement. There is perhaps an erroneous presumption from the public in the phrase: "Look how hurt she is, she's crying." In a humanistic analysis, hurt is instantaneous, and the discharge of tears is the beginning of the healing process.

Have a Willingness to Be Vulnerable: Client and Therapist

The willingness of the therapist to self-disclose invites a present-time encounter. It is not like a cocktail party "can you top this" game where the therapist has a juicier story than the client. Yet, appropriate self-revelation provides a genuineness and says, "I am a person too and I have experienced hurt as well." Some therapists will demur when it comes to any self-disclosure, citing the Freudian notion that the analysis is for the patient and s/he need not know about the therapist. Yet, the ability of the therapist to self-disclose in a way that benefits the client can be healing, and is a product of the therapist's own emotional health. One way to put it is that the therapist needs to have worked through personal issues enough to have "margins of good health" somewhat like the self-actualizing people described by Abraham Maslow (Maslow, 1954). One therapist reported a client who had been in the military, isolated from any female companionship, who engaged in a sexual act with another man. It only happened once, however the client was confused about his sexual orientation. The therapist noted that he then took the interactive risk to say, briefly but with sincerity, that he too had once and only once had such an episode with a man. He said that he stopped after that revelation, yet it seemed to give his client some sense of mutuality.

Be Aware That All Choices Are for Self-Enhancement

To say that people will choose what is perceived as self-enhancing is not to say they are all monuments to selfishness. If a child were in the street and a car were bearing down, one might choose to knock the child away even at the cost of his or her own injury or life. The humanistic therapist honors that behavior is chosen for perceived, valid personal reasons.

If we choose behavior that enhances us, however mysterious to outsiders, then we become responsible for our life conditions. A professor (a personal colleague) once shared that he told his graduate students that people will *always* do what they perceive as most enhancing to themselves, the key word being perceive. In visiting a state mental hospital, he showed his class a young teen, sitting rigid, staring at the wall. The group toured the facility and returned an hour later to see the boy, unmoved, still staring at the wall. One student asked how that could be most self-enhancing, that the boy was hurting himself with that behavior. His humanistic professor replied, "From whose perspective? From an outside view, we might judge the boy, but from his internal perspective, everything else may be more threatening than to pull himself into a ball and sit silently." There is a caution to this notion of personal responsibility, since people are not responsible for things beyond their control: toxins that invade their bodies, acts of nature, accidents, or some misguided leader's misdirected bombs.

Therapy: A Rush To Fix Things?

In these nine operational suggestions, it may be seen that Humanistic therapists have the intent to uplift their clients to their own highest level of functioning. Integrated people (like Thoreau, Gandhi, Cesar Chavez), as noted above, are able to evaluate the panorama of human events they encounter with clear eyes and incisive choices, even if they go against a hallowed rule or sanctified law; they take appropriate emotional risks. Humanistic therapists are aware that they have learned to be therapeutic (and hope their clients have as well) not only in the hours in therapy, but for all their life transactions. In Humanistic promotional language, it is said that one cannot become a therapist without the process being life-changing.

It is an artifact of third-party insurance requirements that present-day therapies may often be limited to a few sessions. The charge is to cure the patient of his or her neurosis quickly and certainly. The possible fallacy in this fiat is that the word "cure" may narrowly mean a cessation of a certain behavior, but with no attention to underlying causes or a deeper sort of malaise. A critique of insurance-driven therapy includes the objection to what is called "labeling." The need for diagnosis is recognized, since there are symptoms that can be attached to certain unproductive behavior. However, it can be damaging to attach a stigmatic name to a person's unhappiness, a label that may follow that person throughout life. Clarity in one's search for authenticity can take a heavy investment of time and energy. Rogers (1987) once noted: "I must constantly resist the temptation to rush in and fix things."

Given the present enormous variety of therapeutic approaches, the application of Humanistic Psychology stands out as one that functions to empower clients rather than fix them. Powerful people will make appropriate decisions to fix themselves. A phrase that has been used in educating therapists is: "If we do our job well, we do ourselves out of a job."

J. F. T. Bugental, AHP's first president, called the humanistic emergence 'The Third Force' in psychology. He noted that human beings are intentional, aim at goals, are aware that they cause future events and seek meaning, value, and creativity (Bugental, 1964).

Cognitive behavioral therapies (CBT) propose a model of general psychopathology and a theory of behavior change that integrates diverse psychotherapeutic procedures, that is sensitive to a biopsychosocial perspective of medical and psychological disorders, and is tied to empirically demonstrated interventions. In the past, various schools of psychotherapy (e.g. psychodynamic, behavioral, and humanistic) have been offered as competing approaches, with little proposed overlap. In recent years, there has been an effort to develop an "integrative" approach of psychotherapeutic techniques that have demonstrated empirical basis of efficacy. CBT has been at the forefront in this integrative movement. CBT has demonstrated the beneficial effects of psychotherapy in not only alleviating distress, but also in reducing the likelihood of subsequent relapse of psychological and behavioral dysfunction (Khanna & Kendall, 2010 Meichenbaum, 1997; Walkup et al., 2008; Whiteside et al., 2016).

What Is CBT?

As Mahoney and Arnkoff (1978) aptly observed, under the heading of CBT are many diverse psychotherapeutic procedures including cognitive therapy, cognitive restructuring procedures, rational-emotive psychotherapy, problem-solving interventions, coping skill training such as stress inoculation training, panic control techniques, and self-instructional training, to name just a few. One should not impose a "uniformity myth" on these diverse therapeutic procedures since they have different theoretical perspectives, different modes of implementation, and have different outcomes.

Despite these differences, there are some common features to all CBT approaches that can be delineated. At the theoretical level, CBT embraces a biopsychosocial perspective that emphasizes the reciprocal interdependence of feelings, thoughts, behavior, resulting consequences, social contexts, and physiological processes, namely, a reciprocally deterministic approach as described by Meichenbaum (1977). Simply, CBT is based on the belief in the connection between thoughts, feelings, and behaviors. The goal in CBT is to modify or change both the client's or patient's thoughts and behaviors. While early CBT theorists have highlighted cognitions as being a central or primary in the psychotherapeutic process, noting that cognitions, in the form of irrational beliefs (Ellis, 1977) or cognitive distortions and errors (Beck, 1976), cause emotional disturbance and maladaptive behaviors, more recent forms of CBT have taken issue with such a rationalist and objective position. As Mahoney (1988) observes, rationalist therapeutic approaches attempt to have patients monitor and correct "disturbed" or "irrational beliefs" and "faulty logic." This rationalist approach attempts to help patients develop more accurate and objective views of reality by such means as logical disputation, instruction, personal experiments, whereby patients can collect empirical evidence in an effort to test their beliefs against external reality.

In contrast, many emergent forms of CBT have embraced a more constructionist perspective (Meichenbaum, 1997). The constructionist perspectives based on the notion that individuals are "architects" or "constructors" of their environments and it emphasizes how individuals behave may inadvertently, perhaps unwittingly, and even unknowingly, create reactions in others that confirm their beliefs about themselves and the world. The constructivist perspective emphasizes that individuals "construct" their personal realities or narrative stories and literally create their own representative models of the world. It is not, as if there is one reality and our patients distort that reality, thereby contributing to their problems. Rather, constructivists propose there are multiple realities, and the task of therapy is to help patients become aware of how they create their realities and the consequences of such personal constructions. The shift from a "rationalist-objective perspective" is not just a shift in semantics but a shift that has important implications for both assessment and treatment.

An additional salient and common feature of CBT is that it tends to be short-term, typically less than 20 sessions, although Linehan (1993) used a one-year CBT intervention to reduce suicidal behavior with borderline patients. No matter what the length of the CBT treatment, the intervention tends to be highly collaborative between patient and therapist, often using Socratic questioning techniques and discovery-based interventions. CBT also tends to be proactive in encouraging patients to use personal experiments or "homework" between sessions. Another common, important feature of CBT interventions is the inclusion of relapse prevention (RP) procedures. While RP was initially emphasized by Marlatt and Gordon (1985) with patients with addictions, RP is typically used with all forms of CBT interventions. In RP, patients explore the nature of high-risk situations that are likely to contribute to lapses and that can escalate into becoming full-blown relapses. In therapy, patients rehearse how to anticipate and manage such lapses.

Finally, CBT is sensitive to the critically important role of the relationship and those emotional factors evident in the therapeutic process. In addition to the collaboration between patient and therapist, salient factors involving warmth, empathy, emotional attunement, acceptance, providing hope, reinforcing patient efficacy, and developing a

therapeutic alliance are all therapist variables emphasized in CBT (Hawton et al., 1989). In summary, CBT across all variations recognizes the importance and inseparability of therapeutic techniques, personal qualities of the therapist, and the nature of the therapeutic relationship.

Historical Perspectives

CBT has two main influences: first, behavior therapy (BT) as described Joseph Wolpe and others in the 1950s and 1960s; and second, the cognitive therapy approach developed by Aaron T. Beck, beginning in the 1960s but becoming far more influential with the "cognitive revolution" in psychology beginning and flourishing in the 1970s and 1980s (Westbrook, Kennerly, & Kirk, 2007).

BT arose as a reaction against the Freudian psychodynamic paradigm that had dominated psychotherapy from the nineteenth century onward. In the 1950s Freudian psychoanalysis was questioned by scientific psychology because of the lack of empirical evidence to support either its theory of its efficacy. BT was strongly influenced by the behaviorist movement in academic psychology, which stipulated that what went on inside a person's mind was not directly observable and therefore not amenable to scientific study and empirical validation. Instead, behaviorists sought reproducible associations between observable events, particularly between stimuli (features or events in the environment) and responses (observable and measurable reactions from the people or animals being studied). Learning theory, a major model in psychology at that time, sought general principles to explain how organisms learn new associations between stimuli and responses. In this way, BT avoided speculations about unconscious process, hidden motivations, and unobservable structures of the mind, and instead used the principles inherent in learning theory to modify unwanted behaviors and dysfunctional emotional reactions. BT rapidly became successful, especially with anxiety disorders, because BT always had an empirical approach, which allowed it to provide solid evidence that it was effective in relieving anxiety problems, like phobias and obsessive-compulsive disorders, and BT was a far more economical treatment than psychoanalytical therapy, typically taking from six to five sessions (Westbrook, Kennerly, & Kirk, 2007).

Despite this success, there remained some dissatisfaction with the limitations of a purely behavioral approach (see Meichenbaum, 1997). Psychological processes such as thoughts, beliefs, interpretations, and imagery, for example, are such an obvious aspect of life that it seemed almost absurd for modern psychology not to deal with these aforementioned processes. In addition, it was believed that once BT techniques were altered to become more sensitive to patients' thoughts and emotions, then treatment efficacy would also improve (Westbrook, Kennerly, & Kirk, 2007).

During the 1970s, this dissatisfaction developed into what became known as the "cognitive revolution," whereas ways were sought to bring cognitive phenomena into psychology, theories of psychopathology, and therapy while still trying to maintain empirical approaches that would avoid ungrounded speculation. Beck, and others like Albert Ellis (1977), began to develop cognitive therapy (CT) during the 1960s but their ideas became increasingly influential by the late 1970s. For example, the publication of Beck's book on CT for depression

(Beck et al., 1979) and research trials demonstrating that CT was effective as a treatment for mild to moderate depression as anti-depressant medication reinforced the revolution. Over the next several decades, BT and CT grew together and influenced each other to such an extent the resulting combination is now most commonly known as CBT. It would appear that CBT has currently emerged as one of the most endorsed and studied therapeutic approaches in psychology (Craighead, Miklowitz, & Craighead, 2013).

Basic Principles

As mentioned previously, CBT proposes a "biopsychosocial" explanation as to how human beings come to feel and act as they do – i.e. a combination of biological, psychological, and social factors become involved. The most basic premise is that all human emotions and behaviors are a result of what individuals think, assume, or believe (about themselves, other people, and the world in general). It is what people believe about situations they face, not the situations themselves that determines how they feel and behave. CBT involves an interacting system where problems can be perceived as interactions between thoughts, emotions, behavior, and physiology, as well as with the environment in which the individual functions. Environment in this premise involves not just the obvious physical milieu for the person but also the social, family, cultural, and economic environment (Froggatt, 2009).

   In ordinary life, if we ask people what made them sad (or happy, or angry, etc.), they will often offer accounts of events or situations: for example, "I am angry because I just had an argument with my spouse." However, it is not that simple. If an event automatically gave rise to an emotion in such a straightforward manner, then it would follow that the same event would have to result in the same emotion for anyone who experienced that same event. What can be actually observed is that to a lesser or greater degree, people will react *differently* to similar events. Even events as obviously terrible as suffering or bereavement, or being diagnosed with a terminal illness, do not produce the same emotional state in everyone: some may be devastated by such events, while others cope reasonably well. If it is not the event, then, that determines the emotional response, there must be additional factors. CBT stipulates that one salient additional factor is cognition or the interpretations people make of the event. When two people react differently to an event it is because they are perceiving it differently, and when one person reacts in what seems to be an unusual or even dysthymic way, it is because s/he has idiosyncratic thoughts or beliefs about the event and the event has idiosyncratic meaning for her/him.

   Another example elaborates on the centrality of cognition in emotional response. Suppose you are walking down the street and you see someone who you know coming the opposite direction, but he/she does not seem to notice you. There are a number of possible thoughts about this event and a number of possible emotional responses arising from those cognitive interpretations. For instance, you could think, (a) "I can't think of anything pertinent to say to her/him, therefore s/he must think I'll really boring," resulting in feelings of anxiety in social situations; (b) "Nobody would ever want to talk to me anyway because no one seems to like me," leading to feelings of depression and/or despondency; (c) "S/he has some nerve being so snobbish, I have not anything wrong to deserve this," resulting

in feelings of anger, and (d) "S/he is probably still hung over from the party last night!" leading to feelings of amusement. This emotional episode consists of an activating event ("A"), beliefs ("B") about the activating event ("A"), and the consequences ("C") in both emotions and behaviors. Therefore, "A" does not necessarily cause "C"; "A" triggers "B"; "B" then causes "C." Such ABC episodes developed by Ellis (1977) do not stand alone and will run in chains with a "C" often becoming the "A" of another episode. Humans observe our own emotions and behaviors and react to them. For instance, the person in the example above could observe their avoidance of other people ("A"), interpret this as weak ("B"), and engage in self-doubting ("C").

From this example alone, several different cognition interpretations can give rise to several different emotions. It also demonstrates the association between certain kinds of cognition and corresponding emotional states. For example, thoughts about others being unfair, or breaking rules that we may hold dear, are likely to be associated with anger. There is, of course, nothing new about the idea that meaning and cognition are crucial. The ancient Greek stoic philosopher, Epictetus, proposed over 1,880 years ago that, "Men are disturbed, not by things, but by the principle and notions which they form concerning things" (Westbrook, Kennerly, & Kirk, 2007, p. 4).

CBT supports the premise that behavior can have a strong impact on thought and emotion, and, in particular, changing what you do is often a powerful way of changing both thoughts and emotions. CBT also supports the premise that psychological problems arise from exaggerated or extreme versions of normal processes, rather than as pathological states that are qualitatively different from, and inexplicable by, normal states and processes (Westbrook, Kennerly, & Kirk, 2007). In other words, psychological problems can be conceptualized at one end of a continuum, not in a different dimension.

Furthermore, CBT has incorporated a BT approach that the main focus of treatment, for most of the time, involves what is happening in the "here and now" or in the present. Therapy focuses on those processes currently maintaining the problem, rather than the processes that might have led to its development many years ago. Psychoanalytic proponents have argued that treating symptoms rather than the supposed root causes would result in symptom substitution or the emergence of new client symptoms secondary to unresolved unconscious conflicts. Extensive BT research, however, demonstrated that, although possible, such findings were, in fact, rare. More commonly addressing symptoms directly actually resulted in more global improvement. Finally, CBT is based on empirically valid, sound, well-established scientific theories. Ethically, recipients of CBT should know whether treatments they receive are effective. Economically, recipients of CBT should also know that limited mental health resources are being used in a cost-effective manner (Westbrook, Kennerly, & Kirk, 2007).

Levels of Cognition

As described previously, "cognition" is not a single concept. Instead, CBT distinguishes between different levels of cognition that often serve as a means of classifying various CBT techniques. Some common levels of cognition in CBT are briefly described here.

Negative Automatic Thoughts (NATs)

NATs, as first described by Beck (1976), are fundamental to CBT. The term describes a stream of thoughts that are negatively tinged appraisals or interpretations or meanings individuals take from what happens around them or within. For example, if one is anxious, one might have thoughts about the threat of something bad happening to themselves or people one cares about; if one is annoyed, one might have thoughts about others being unfair, or not following rules one considers important; if one were angry, there might be thoughts about loss, personal defeat, or negative views of oneself.

NATs can exert a direct influence over mood from moment to moment and are of crucial importance to CBT. Subsequently, NATs are often focused on early in treatment. NATS will often just happen, automatically, and without effort (although it may take some effort in treatment to focus on them). In chronic problems, NATs tend to be stereotypic, but they can vary in frequency, intensity, and duration. NATs can be habitual and often seen as plausible and true, especially when emotions are intense. One crucial step in CBT is to help patients consider the accuracy of their NATs by learning that thoughts are opinions and not facts, and like all opinions, they may not be accurate. At first it appears that NATs are verbal constructs (e.g. "I am useless") but, in fact, can also take the form of visual images, as can be observed in social anxiety where the patient may also have a mental image of themselves looking red-faced, sweaty, and speaking incoherently at a party.

Core Beliefs

Core beliefs represent individuals' fundamental beliefs about themselves, other people, or the world, in general. Most of the time core beliefs are not immediately conscious but can be inferred by observations of one's characteristic thoughts and behaviors in various situations. Core beliefs can be observed as general and absolute statements (e.g. "I am incompetent" or "others cannot be trusted"). Unlike NATs, core beliefs do not vary across times or situations but are seen by the individual as fundamental truths to be applied in all situations. They are usually learned early in life secondary to childhood experiences, but can develop or change later in life, for example, as a result of trauma. Core beliefs are often dealt with later in CBT and can be important in therapy for chronic disorders, such as personality disorders (Westbrook, Kennerly, & Kirk, 2007).

Dysfunctional Assumptions (DAs)

DAs can be considered rules for living and functioning and can serve to bridge the gap between NATS and core beliefs. They often take the form of conditional "if...then" propositions, or are framed as "should" or "must" statements, and represent attempts to function with negative core beliefs. What makes DAs dysfunctional is they are too rigid and over generalized, not flexible enough to cope with the inevitable complications and setbacks in life. Some DAs may be culturally reinforced, such as putting others first or the importance of success, for example. Modifying DAs often assist in making patients more resistant to future relapses and thus are dealt with in the later stages of CBT. For example, if a patient believes that s/he is fundamentally unlovable may develop the faulty assumption that

"If I always try to please others, then I will be tolerated," but "If I assert myself, possibly displeasing others, I will be rejected." This DA offers the patient a guide to live her/his life as to overcome some of the feared effects of the core belief, but this is both a fragile and futile effort. If the patient fails to please someone, then the patient is in trouble. When a DA is violated, then NATs and strong dysphoric emotions are likely to be triggered (Westbrook, Kennerly, & Kirk, 2007). While core beliefs are more general than NATs, that does not mean they are more important. Most successful CBT research targets NATs, but that does not make therapy ineffective or short-lived. Patients with problems like depression or anxiety have a range of core beliefs, not just negative or dysfunctional ones. CBT also assists in bringing patients, more positive beliefs back into prominence. This may be especially pertinent to those patients with coexisting, long-term personality disorders where there is often a paucity of positive beliefs (Tolin, 2016).

CBT theories include characteristic patterns of cognition associated with particular kinds of problems. These characteristic patterns involve both the content of cognition and the process of cognition. In depression, for example, the thoughts of depressed people are likely to contain characteristic contents, e.g. negative thoughts about themselves or others. Depressed people are also likely to show characteristic general biases in the way they think, e.g. toward perceiving and remembering negative events more than positive ones; or tending to see that anything that goes wrong their fault; or overgeneralizing from one small negative event to a broad negative conclusion.

In anxiety, the general process is a bias toward the overestimation of threat or perceiving a high risk of some unwanted outcome. The exact nature of the threat, and therefore the content cognitions, is different in different anxiety disorders. For example, in panic disorder, there is catastrophic misinterpretation of harmless anxiety symptoms as indicating some imminent disaster such as dying or losing all control of oneself. In health anxiety, there is a similar misinterpretation of harmless physical symptoms as indicating severe illness, but on a longer duration (e.g. "I might have a disease that will eventually cause me to die"). In social anxiety, thoughts generally involve being negatively evaluated by others (e.g. "they will think I am stupid or boring or strange should I speak"). Finally, in obsessive-compulsive disorder, for example, thoughts are typically about being responsible for and/or needing to prevent some harm to oneself or others (Westbrook, Kennerly, & Kirk, 2007).

In summary, Westbrook, Kennerly, and Kirk (2007) note that CBT proposes that through experience (most often childhood experience, but sometimes later experiences as well), individuals develop core beliefs and assumptions that are typically functional and allow them to make sense of life and manage through it. Most individuals have a mixture of functional and dysfunctional beliefs, with the functional ones allowing them to cope reasonably well most of the time. Even dysfunctional beliefs may not cause particular problems for many years. However, if one should encounter an event or series of events that violates a core belief or assumption and cannot be managed by more positive beliefs (often called a "critical incidents"), then DAs become more salient and active. Negative thoughts are evoked, and unpleasant, dysphoric emotional states such as anxiety or depression result. Interactions between negative thoughts, emotions, behavior, and physiological changes may then result in persisting dysfunctional patterns and vicious cycles or feedback loops that serve to reinforce and maintain the problem. In summary, Tolin (2016) identified several of the core essentials inherent in CBT to include: (a) having reasonable

and meaningful goals for treatment; (b) using the best scientific evidence in understanding the problem, and selecting empirically valid approaches to treat the problem; (c) using hypothesis testing that may need to be modified for accuracy in treatment; (d) being focused, time-limited, present-oriented, active, and directive emphasizing measureable goals and testable hypotheses; and (e) identifying the core pathological process as the interaction among maladaptive behaviors, thoughts, and emotions.

Applications and Efficacy

Space does not permit a detailed meta-analysis of numerous CBT procedures for diverse populations. A number of comprehensive reviews are available (e.g. Meichenbaum, 1997; Butler, Chapman, et al., 2006; Westbrook, Kinnerly, & Kirk, 2007; Hofmann & Smits, 2008; Hofmann, Asnaani, Vonk, et al., 2012; Craighead, Miklowitz, & Craighead, 2013; Tolin, 2016; Whiteside et al., 2016). This section will provide a broad overview of a wide variety of efficacious applications of CBT with adult populations, followed by some additional examples demonstrating the efficacious application of CBT with youth and international populations.

Roth and Fongay (2005), in their review of psychotherapy efficacy, report evidence showing that CBT is strongly supported as a therapy for most of the psychological disorders in adults that they studied, and has more support in more kinds of problems than any other therapy. In addition to the evidence for efficacy with CBT in well-controlled research trials, there is also evidence demonstrating that it can also be effective in clinical practice, outside specialized research centers (e.g. Tolin, 2016).

Leahy (2003) identified over 30 specific techniques used in CBT. Some common techniques used in CBT include: (a) cognitive techniques (e.g. rational analysis, disputation, catastrophe scaling, role playing, reframing); (b) imagery techniques (e.g. time projection, "worst-case" scenario technique); (c) behavioral techniques (e.g. exposure, desensitization, hypothesis testing, stimulus control, paradoxical behavior, delayed gratification, contingency management, modeling); (d) skill training (e.g. self-instruction, relaxation exercises, biofeedback training, mindfulness and meditation training, social skills, problem-solving); and (e) record, log, journal, and diary keeping for self-education. In addition, Froggatt (2009) identified numerous clinical problem areas where CBT has been used with specific populations. These problem areas include: depression; bipolar affective disturbances; anxiety disorders (obsessive-compulsive disorder, phobias, generalized anxiety disorder, posttraumatic stress disorder, hypochondria and health anxiety); psychosis and schizophrenia; eating disorders; weight control; addictions; smoking cessation; sexual dysfunction; impulse control disorders; anger management; antisocial disorders; sexual abuse recovery; personality disorders; adjustment to chronic health problems and physical disability; pain management; general stress management; child and adolescent behavior disorders; and relationship and family problems. The most common use of CBT continues to with individual patients and clients (including children, adolescents, and adults), but this is closely followed by group work, for which CBT can be also well suited. CBT can also be used with couples and families (Froggatt, 2009).

Butler, Chapman et al. (2006) summarized the meta-analysis literature on treatment outcomes of CBT for a wide range of psychiatric disorders. A search of the literature resulted in a total of 16 methodologically rigorous meta-analyses. The authors' review focuses on effect sizes that contrast outcomes for CBT with outcomes for various control groups for each disorder, which provides an overview of the effectiveness of CT as quantified by meta-analysis. Large effect sizes were found for CBT for unipolar depression, generalized anxiety disorder, panic disorder with or without agoraphobia, social phobia, posttraumatic stress disorder, and childhood depressive and anxiety disorders. Effect sizes for CBT of marital distress, anger, childhood somatic disorders, and chronic pain were in the moderate range. CBT was somewhat superior to antidepressants in the treatment of adult depression. CBT was equally effective as BT in the treatment of adult depression and obsessive-compulsive disorder. Large uncontrolled effect sizes were found for bulimia nervosa and schizophrenia. The 16 meta-analyses reviewed support the efficacy of CBT for numerous psychological disorders.

Hofmann and Smits (2008) noted a weakness of meta-analyses involving psychotherapy research is related to the quality of the original studies. In particular, a number of frequently cited meta-analyses of CBT for anxiety disorders have included studies that vary greatly with respect to control procedures, which range from waitlist, alternative treatments, and placebo interventions that were evaluated with or without randomization. Other studies fail to include any control groups. Subsequently, the authors argue the results of most existing meta-analyses of CBT for anxiety disorders, for example, are of limited validity because the quality and rigor of meta-analyses is directly related to the quality and rigor of the studies that are included in these analyses.

The gold-standard design in clinical outcome research is the randomized placebo-controlled trial. Although not without problems, this design has been used as the primary test of the direct effects of the treatment on outcome in clinical research. Pharmacotherapy trials, for example, typically administer a sugar pill to individuals in the placebo condition. Instead of including a pill placebo, a number of psychotherapy trials have employed psychological placebo conditions to control for nonspecific factors. Although it is difficult, if not impossible, to protect the blind in placebo-controlled psychotherapy trials, the randomized placebo-controlled design is still the most rigorous and conservative test of the effects of an active treatment.

The primary aim of the Hofmann and Smits (2008) study was to determine the acute efficacy of CBT as compared to placebo for adult anxiety disorders. In contrast to existing meta-analyses of CBT for anxiety disorders, the authors limited their selection to randomized placebo-controlled trials of DSM-III-R or DSM-IV anxiety disorders that directly compared the treatment efficacy of CBT with a placebo condition. The authors further expanded their search to all types of anxiety disorders in order to compare the effects of CBT for the various anxiety disorders and explored the potential moderating effects of number of treatment sessions, placebo modality (pill vs. psychological placebo) and publication year. The strongest effect sizes were observed in obsessive-compulsive disorder and acute stress disorder, and the weakest effect size was found in panic disorder. The advantage of CBT over placebo did not depend on placebo modality, number of sessions, or study year. Hofmann and Smits (2008) review of randomized placebo-controlled trials indicated that CBT is efficacious for adult anxiety disorders.

Hofmann, Asnaani, Vonk et al. (2012) provided a comprehensive survey of meta-analyses also examining the efficacy of CBT. The authors identified 269 meta-analytic studies and reviewed of those a representative sample of 106 meta-analyses examining CBT for the following problems: substance use disorder, schizophrenia and other psychotic disorders, depression and dysthymia, bipolar disorder, anxiety disorders, somatoform disorders, eating disorders, insomnia, personality disorders, anger and aggression, criminal behaviors, general stress, distress due to general medical conditions, chronic pain and fatigue, and distress related to pregnancy complications and female hormonal conditions. Additional meta-analytic reviews examined the efficacy of CBT for various problems in children and elderly adults. The strongest support existed for CBT of anxiety disorders, somatoform disorders, bulimia, anger control problems, and general stress. Eleven studies compared response rates between CBT and other treatments or control conditions. CBT showed higher response rates than the comparison conditions in seven of these reviews and only one review reported that CBT had lower response rates than comparison treatments. In general, the evidence-base of CBT is very strong. However, the reviewers noted additional research is needed to examine the efficacy of CBT for randomized-controlled studies. Moreover, except for children and elderly populations, the authors noted no meta-analytic studies of CBT have been reported on specific subgroups, such as ethnic minorities and low-income samples.

The relative effectiveness of CBT is not limited to psychiatric disorders, but has been expanded to physical disorders as well. Turk and Salovey (1993) reviewed over 15 controlled studies demonstrating the effectiveness of CBT interventions for a wide range of physical illnesses and disabilities including headaches, arthritis, tempomandibular pain disorders, low back pain, spinal cord injuries, functional somatic symptoms, and cancer, to name a few. These approaches have been used successfully with patients across the age span from adolescents to geriatric patients. Finally, Meichenbaum (1997), in his review of several controlled studies demonstrating the effectiveness of CBT approaches with medical patients, also highlighted the additional benefit of reduced medical utilization costs when CBT was utilized.

Noting the wide range of emotional and behavioral problems manifested by youth, both children and adolescents, CBT is an effective and proven therapeutic approach (Hughes, 1988; Webb et al., 2014). When considering the application of CBT with children and adolescents, current research has demonstrated strong efficacy for its use across a variety of diagnostic issues including anxiety, trauma, insomnia, and suicide. Further, there are several studies that also demonstrate a high degree of efficacy when using CBT with children or adolescents from various other countries including Tanzania and Kenya (Woods-Jaeger, Kava, Akiba, Lucid & Dorsey, 2016), Switzerland (Schneider et al., 2013), and the Netherlands (van Steensel & Bögels, 2015). However, it should be noted that the application of CBT, or any other theoretical approach with children and adolescents is not a simple one-to-one conversion from those used with adults. Kendall (2013) states "Youth face different developmental challenges as they move through childhood and adolescence, and these youth differ in their ability to recognize a problem, manage their emotional arousal, and to generate and consider possible solutions" (p. 4). This requires the understanding and adaptation of CBT treatments and interventions to consider not only the specific disorder, but also based upon the youth's current developmental level. Requiring

the practitioner to be aware of and consider the current developmental stage of their young client is a critical component to success when working with young populations.

When considering examples of current CBT treatment approaches with various psychological disorders, the research literature is replete with a wide range of examples, of which most demonstrate a positive impact. For example, for the treatment of childhood anxiety disorders the American Academy of Child and Adolescent Psychiatry (AACAP) (2007) lists CBT as the preferred evidence-based treatment. Numerous studies have shown the positive impact of using CBT for treating anxiety in youth (e.g. Kendall, Hudson, Gosch, Flannery-Schroeder & Suveg, 2008; Khanna & Kendall, 2016; Walkup et al., 2008; Whiteside et al., 2016). Further, Cummings et al. (2013) demonstrated that it is not only CBT itself, but also the strength of the therapeutic alliance which then leads to more positive outcomes when using CBT to treat childhood anxiety.

Considering the recent study by Khanna and Kendall (2016), the researchers tackled several issues involved in the practice and application of CBT with a population of youth between the ages of 7 and 13 years. With previous research demonstrating the efficacy of CBT treatments for youth with anxiety disorders, Khanna and Kendall focused on the question of bringing CBT treatment to a community setting with limited mental health providers available. By using a computer-assisted CBT program, they were able to demonstrate a statistically significant positive impact, compared to a control group, immediately after the intervention ended, as well as three months later. Thus, not only demonstrating that the particular CBT intervention they used was effective for youth with anxiety disorders, but also Khanna and Kendall (2016) demonstrated that CBT could be delivered via a computer-assisted program, reducing overall costs and making the treatment more accessible to more communities.

Related to anxiety, the use of trauma-focused CBT treatment with victims of trauma has also been shown to yield positive results (e.g. Cohen, Mannarino, & Deblinger, 2012; Gil & Jalazo, 2009; Misurell et al., 2014). Although these studies have the common theme using trauma-focused CBT, they each take a very different approach. For example, the work of Misurell and his colleagues (Misurell et al., 2014) is centered on game-based CBT with youth between the ages of 4 to 17 years who have experienced child sexual abuse. By using an integrative approach to bridge evidenced-based structured play therapy with cognitive BT, they demonstrated how this intervention was able to improve treatment engagement and interest amongst the children and adolescent participants. Cohen et al. (2012) discusses trauma-focused CBT in a broader sense, synthesizing the research around the utility of songs, games and other creative activities to build receptivity toward the treatment prior to engaging in CBT in order to enhance treatment gains amongst youth. The integration of play therapy with trauma-focused CBT has also shown positive results (Gil & Jalazo, 2009).

Shirk et al. (2014) evaluated the effectiveness of a modified CBT approach with adolescents who had been exposed to a traumatic event and also presenting with depression. Noting previous research that indicated this particular population struggles to show much improvement with a variety of treatment approaches, they modified a CBT approach to focus on both cognitive deficits and distortions found among youth exposed to interpersonal trauma, resulting in a significant reduction in depressive features and high levels of satisfaction with the treatment. However, symptom reduction results were similar to those in the control group.

When adolescents struggle with insomnia, not only does it inhibit their ability to lead a productive life, but also interferes with critical learning that occurs in the teen years, including social skills and academics (Palermo et al., 2016). Insomnia and CBT has been studied and applied successfully for years with adult populations, but little research has been conducted on its effectiveness with adolescents. Recent research by Palermo et al. (2016) demonstrated the successful application of CBT with adolescents between the ages of 11 and 18 years suffering from insomnia in only four CBT treatment sessions.

Another study using a brief CBT approach to treatment, Bryan and colleagues (Bryan et al., 2012) described the process of treatment completion, i.e. termination of services, with a previously suicidal youth population. Specifically, they outline the various steps necessary for the client to complete within a brief CBT-focused treatment approach in order to reach the stage to begin termination of treatment, i.e. met success. This approach demonstrates the effectiveness of not only the use of a CBT approach in therapy with youth, but also for both the practitioner and client to reach an understanding when the treatment has been successful and it is time to terminate.

In addition to specific disorders, research has also demonstrated the use and effectiveness of CBT with children and adolescents from various populations. For example, several studies have shown positive results when using CBT with youth who have been diagnosed as high functioning along the autism spectrum disorder (ASD) and anxiety (e.g. Chalfant, Rapee, & Carroll, 2007; Reaven, Blakeley-Smith, Culhane-Shelburne, & Hepburn, 2012; Reaven et al., 2008; Sofronoff, Attwood, & Hinton, 2005; Wood et al., 2009). Post-treatment interviews have reported one-half to three-fourths to be free of previously noted anxiety disorder symptoms (Chalfant et al., 2007; Wood et al., 2009). Of more importance, it was noted in several studies that in addition to the reduction of anxiety symptoms, there were also decreases in general ASD problematic behaviors (Wood et al., 2009) and increases in positive skills like independence and daily living skills (Drahota, Wood, Sze, & Van Dyke, 2011).

When considering the use of CBT with international populations, van Steensel and Bögels (2015) demonstrated the effectiveness of CBT for anxiety disorders in youth, ages 11–18 years, with ASDs in the Netherlands. With over 200 participants in seven community-based clinics, the researchers found that a standard CBT protocol was as effective with their anxious ASD population as reported in other anxious-non-ASD populations. However, when comparing the treatment with an ASD population without an anxiety disorder, the treatment was seen to be mildly effective, impacting only a few of the targeted ASD behaviors the researchers hoped would improve. While in Switzerland, Schneider et al. (2013) compared the effectiveness of CBT interventions with Swiss children between the age of 8 and 13 years suffering from separation anxiety disorders. One of the CBT interventions included parents while the other did not have parental involvement. As would be expected, the engagement of parents led to better treatment results than the nonparental involved CBT treatment for these Swiss children.

A qualitative study completed in Tanzania and Kenya focused on learning how best to develop a culturally responsive, trauma-focused CBT treatment approach with youth (Woods-Jaeger et al. 2016). The authors systematically interviewed local community-based lay counselors who worked directly with children between the ages of 7 and 13 years in both countries, as part of two other larger studies. Their results indicated that when using a trauma-focused CBT approach in either of these countries, the provider should first understand the

cultural norms, then discuss with their guardians what has already been attempted and the level of success attained. Additionally, it was noted how critical it was for the agency to help take care of basic needs of the child and family throughout the CBT intervention.

In summary, CBT has repeatedly been demonstrated to be an effective treatment approach with youth, both children and adolescents, struggling with a variety of disorders and from across the world. However, as the research has demonstrated, youth provide unique challenges that must first be understood and then incorporated into any CBT treatment approach. Some of the challenges include developmental issues, both physical and mental, social context including school and home, as well as the family as a support system. It is imperative that prior to engaging in CBT treatment with youth, the provider should first understand the research and application of the CBT treatment based on the age, developmental levels, and other related factors of the youth being served.

Conclusion

The history of CBT has been marked by strong commitments to research on psychosocial processes, sound empirical evaluations, and theoretical development. Future directions for CBT involve its use and efficacy with specific populations, computerization and telehealth, as well as with additional and specific disorders such as insomnia and posttraumatic stress disorders (PTSD) in specific situations. The field of psychotherapy has evolved, establishing and maintaining an integrated, biopsychosocial perspective, and has demonstrated effective empirical procedures. CBT has played and will continue to play, a pivotal role in these accomplishments and developments.

Social Anxiety and Social Anxiety Disorder

Stefan G. Hofmann[1] and Leigh A. Andrews[2]

[1] *Boston University*
[2] *University of Delaware*

Social anxiety disorder (SAD) is characterized by an excessive fear of negative evaluation invariably provoked by exposure to social or performance situations (American Psychiatric Association, 2013). Individuals with SAD are generally aware that their fears are disproportionate to any actual threat inherent in social settings, but still tend to avoid these situations or to endure them while experiencing high levels of distress (Weeks, Heimberg, Rodebaugh, & Norton, 2008). The disorder usually emerges during late adolescence or early adulthood and follows an unrelenting course if left untreated, additionally, it is among the most common psychiatric disorders in the United States, with a 12-month prevalence rate of 7.1% and a lifetime prevalence rate of 12.1% (Kessler, Petukhova, Sampson, Zaslavsky, & Wittchen, 2012). SAD can impose a substantial emotional and professional burden on its sufferers and should be targeted for treatment by the health-care systems (Katzelnick et al., 2001). For a clinical diagnosis of SAD, one must experience significant impairment resulting from avoidance of anxiety provoking social situations. Many individuals with SAD experience increased awareness of physical symptoms (e.g. blushing, sweating, fidgeting, etc.) and believe that those around them are aware of these symptoms as well (Anderson & Hope, 2009). In severe cases, people with SAD believe that they are the object of social attention and are being negatively judged by others.

Those afflicted with SAD frequently describe experiencing extreme shyness, anxiety regarding negative evaluations, school refusal, or some form of separation anxiety as children. In contrast to the other anxiety disorders, which are often predominantly found in women, the prevalence rates for SAD are roughly equivalent across the sexes. SAD is additionally associated with high rates of psychiatric comorbidity, with estimates as high as 83% in clinical samples (Goisman, Goldenberg, Vasile, & Keller, 1995). The most frequent comorbid diagnoses of SAD are MDD, GAD, and substance abuse. SAD is also an undertreated disorder, despite its severity.

Recent years have witnessed the emergence of several theoretical models of SAD. These models offer noticeably different conceptualizations of this syndrome, but share an emphasis

on the role of maladaptive cognitive and behavioral processes in the maintenance of the disorder (Hofmann, 2008). The most effective psychological interventions for SAD are cognitive behavioral therapies (CBT).

Two important commonalities of these approaches are the emphasis of maladaptive cognitive processes and negatively reinforced avoidance behaviors. It has been suggested that people with SAD may be apprehensive in social situations because of excessively high standards for social performance, overestimation of negative social costs, and the reinforcing deployment of safety behaviors. When confronted with perceived social threat, individuals with SAD typically create a mental representation of themselves and how others are perceiving them, leading to increased self-focused attention (Hofmann, 2008). This, in turn, has a number of consequences, as described below.

Negative Self-Perception

Contemporary treatment approaches target the consequences of excessively allocating attention to oneself during social encounters, resulting in an increased awareness of both one's anxious thoughts and internal sensations. Research suggests that in situations of heightened self-focused attention, people with SAD experience overly negative self-perceptions of their performance, which further confirms their beliefs that they are unable to convey the competent impression of themselves to others that they wish to convey (Bögels, 2006). Such perceptions tend to become reinforced through inaccurate information processing in social contexts, which can also inhibit subsequent behavioral performance.

Individuals with SAD also have attention biases toward socially threatening stimuli and away from more positive social cues. These attention biases can contribute to the impairing cycle of self-focused attention and negative performance. Furthermore, individuals with SAD tend to dismiss the value of their accomplishments when evaluating their behavior, even when they have performed adequately (Hofmann & Otto, 2008).

Social Standards

People with SAD typically presume that a very high level of performance is expected of everyone during social situations. This belief is usually accompanied by concerns about lacking the competence necessary to meet other's expectations, which compels socially anxious individuals to constantly compare their performance with these high standards (Hofmann, 2008). Many individuals with SAD express disappointment about being unable to live up to what they perceive as the high social standards of those around them. The greater the discrepancy between one's perception of one's performance and one's high expectations the more anxiety the individual will feel. Furthermore, even receiving positive input from the audience may cause a socially anxious individual distress, as it can trigger the belief that standards of performance have increased even further (Weeks et al., 2008). Interestingly, when it is clear to the individual that performance standards are low, no differences are found between participants with SAD and nonclinical controls, indicating that excessive negative self-appraisals become activated in people with SAD only during instances with demanding or uncertain performance expectations.

Social Deficits and Social Costs

Early theories postulated that social anxiety emerged as a consequence of social skills deficits, but empirical evidence provides little support for this assumption (Herbert, Gaudiano, Rheingold, Myers, Dalrymple, & Nolan, 2005). For decades, social skills training was a popular intervention for SAD, which did show some therapeutic efficacy (Wlazlo, Schroeder-Hartwig, Hand, Kaiser, & Münchau, 1990). In fact, more recent work has shown that upon successful treatment people with SAD do report improvements in both symptom severity and negative self-evaluations of their own performance during a social situation, but observers noticed no differences in actual social performance from others in a waitlist control. The clinically significant improvement seems to be more the result of altering perceptions, and currently many suggest that social skill training is more effective because of the exposure it requires (in practicing new skills) rather than the training itself (Herbert et al., 2005).

Overestimation of social costs, another key maintenance factor in SAD, reflects an exaggerated concern of assuming that social mishaps would lead to longer-term and irreversible negative consequences (Hofmann, 2008). Research has demonstrated that socially anxious individuals usually regard others as being critical and harsh in their social evaluations, believe that negative social outcomes will happen to them more than positive social outcomes, and rate all social mishaps as more costly. Additionally, several studies have suggested that change in estimated social cost during treatment is a mediator of the reduction in social anxiety symptoms.

Rumination and Post-Event Processing

People with SAD typically engage in rumination after encountering a social situation, which entails an exhaustive review of the social interaction in detail. Past experiences of anxiety and one's own negative self-perceptions frequently come to mind during this post-event processing, which undermines self-efficacy and exacerbates symptoms of overall social anxiety. It can also compel individuals to characterize a positive social interaction as increasingly negative during the course of the rumination (Hofmann & Otto, 2008). Participants reporting high levels of social anxiety exhibit greater levels of post-event rumination following a conversation with an unknown stranger than those who reported lower levels of social anxiety. Even weeks after a social speech task, participants with SAD will maintain increasingly negative self-appraisals of their performance, while non-clinical controls endorse positive self-appraisals of their performance which only improve over the course of the time period. Thus, it seems that post-event rumination may reinforce negative self-evaluations and maintain the vicious cycle.

Safety Behaviors and Avoidance

Social anxiety is often maintained because patients with SAD use avoidance strategies, prohibiting extinction learning. Some of these avoidance strategies involve the use of safety behaviors as a means of temporarily reducing emotional distress or concealing overt

displays of anxiety are a primary factor in the maintenance of SAD. The use of these avoidance behaviors (like avoiding eye contact, over preparing, fidgeting, etc.) prevents people from receiving any information that challenges their beliefs about the likely social costs of their behavior, and reinforces their belief that avoidance is necessary to prevent catastrophic outcomes. Individuals with SAD who are encouraged to undergo exposure while suppressing safety behaviors experience fewer negative self-appraisals and demonstrate greater accuracy in judgments of their own performance than those who undergo exposure alone (Hofmann, 2008).

Effective treatment for SAD targets all of the components presented above, including poor self-image, overestimation of the likelihood of a feared outcome, and the perceived social cost of a negative outcome (Hofmann & Otto, 2008). Psychoeducation prepares patients to actively engage in their treatment through coming face to face with their misconceptions about SAD and through explaining the rationale behind subsequent exposure exercises. Other strategies emphasize attentional modification to address the negative biases discussed above. Training people to redirect their attention to different stimuli while in an anxious situation and to become more present in the moment can help them to perform better and to gain a better understanding of their own anxiety. Another treatment element involves identifying and challenging maladaptive and inaccurate expectations about the likelihood and cost of negative evaluations. Helping people to understand the ways in which their assumptions are inaccurate and encouraging them to consider alternative beliefs is key to correcting the negative feedback loop that maintains SAD.

The most important element in the treatment of SAD, however, is exposing patients to their feared social or performance situations while discouraging safety behaviors. During an exposure, patients are encouraged not to engage in avoidance behaviors but rather to accept the present moment and thereby cope with their feelings of anxiety. Exposures provide an opportunity for individuals to learn that social situations are not inherently threatening. Exposures making use of video or audio feedback can also help to test patients' poor self-concept and their false beliefs concerning how they appear in social situations by comparing their predicted presentation to the actual presentation (Warnock-Parkes, Wild, Stott, Grey, Ehlers, & Clark, 2016). In vivo exposures, or exposures that involve patients directly confronting the feared situation in the real world (e.g. trying to make a return in store), allow patients to test their faulty assumptions about the likelihood and cost of a negative outcome in that social situation. Essentially, exposure serves both as a testing ground for the tools learned from psychoeducation, attention modification, and cognitive biases, as well as its more obvious role in exposing the patient to their fear and beginning to reduce the severity their anxiety.

Future Directions

Future research needs to target the various maintenance factors in SAD and to better understand how they interact in each individual in the maintenance of the disorder. It will be vital to determine for whom these interventions are most efficacious and to tailor our empirically supported treatments to maximize therapeutic benefit.

Personality and Depression

Sally H. Chung

Bellevue, WA

Diagnostic Features

Depressive personality, also known as dysthymic disorder, features a chronic, low-level depression beginning in young adulthood or adolescence that does not occur exclusively during major depressive episodes. Negative thoughts and feelings include persistent feelings of dejection, gloominess, cheerlessness, and unhappiness. Such individuals feel as if they do not deserve fun or happiness. They may be overly serious, at times hostile, self-critical, neurotic, anxious, perfectionistic, lack a sense of humor, dwell on worries and concerns, and have difficulty relaxing. They view the future pessimistically, anticipate the worst, believe that things will not improve, and that they have no power to change their circumstances. They have low self-esteem, judge themselves harshly, and have strong feelings of inadequacy. Individuals with depressive personality often judge others by the same standard as they hold themselves and focus on others' failings rather than positive attributes. They may constantly pull for reassurance or validation, which, coupled with self-loathing, is often what eventually causes others to leave, which reinforces their negative view of the world and their ability to have positive relationships.

The *Diagnostic and Statistical Manual of Mental Orders, Fourth Edition* (DSM-IV-TR) (American Psychiatric Association, 2000) states that an individual must exhibit at least five of the following seven criteria for depressive personality disorder (DPD): (1) usual mood dominated by gloominess, sadness, or cheerlessness; (2) self-concept focuses on inadequacy, worthlessness, and low self-esteem; (3) is given to being critical, blaming, or judgmental toward self; (4) brooding and worries a lot; (5) is negativistic, critical, and judgmental toward others; (6) is pessimistic; and (7) prone to feelings of guilt and/or remorse. The second part of the criteria mandates that the above cognitions and behaviors do not exclusively occur during a major depressive episode or are not better accounted for by the criteria for dysthymic disorder (as stated in DSM-IV-TR). The DPD workgroup for DSM-V recommended that DPD be diagnosed by "core impairment in personality functioning and... pathological personality traits," specifically pessimism, anxiousness, depressivity, low self-esteem,

guilt/shame, and anhedonia. To ensure clarity, dysthymic disorder (renamed persistent depressive disorder in DSM-V) will be referenced as dysthymia for the remainder of this entry.

Within the depressive personality prototype are several variations of interpersonal patterns and internal dynamics observed during social engagement (Rasmussen, 2005). The *restive depressive* personality variation includes traits from the avoidant personality style. These individuals are distressed by their social isolation and blame themselves for the lack of meaningful relationships in their lives. They desire a partner, but feel unworthy of another's attentions or believe that they would ruin a relationship should they ever find one. This results in terminated relationships because of the depressing nature of the relationship. Such individuals may be prone to major depression, dysthymia, and anxiety. They are also more vulnerable to suicidal ideation, attempts, and execution, due to their belief that suicide will provide relief from their continued anguish.

The *self-derogatory depressive* personality style appears to combine the depressive and dependent personality styles. The defining emotion in this variation is guilt related to their inability to cultivate and sustain interpersonal relationships. These individuals tend to be highly self-critical and self-blaming. They want others to reassure and validate them; however, the reassurance often produces more self-loathing in effort to attain more validation, begetting a vicious cycle. Even though other people may see positive personality attributes, they ultimately leave as a consequence of the individual's constant need for reassurance. This results in reinforcing the individual's guilt and self-loathing.

The *ill-humored depressive* personality style incorporates features of the negativistic personality style. These individuals are cynical, bitter, self-pitying, foul-tempered, and irritable. They enjoy watching people fail. They also enjoy complaining and become defensive and argumentative if anyone responded or reframed their grievances optimistically. Compared to other depressive personality variants, people are most likely to avoid those of this style.

The *voguish depressive* personality style includes attributes from the histrionic and narcissistic personality styles. This depressive personality variant believes that unhappiness and negativity are a popular mode of social disengagement and social superiority. Depression is glorified and dignified; if one was not depressed, then one would be considered insensitive to the injustices of the world. Treatment may go one of two ways with this subtype: (1) some may enter therapy to validate their disillusionment of the world; and (2) others may feel it is a waste of time when the world is as badly off as it is. This population may also be at risk for substance abuse disorders due to participation in countercultural activities.

Finally, the *morbid depressive* personality style has masochistic personality traits. These individuals appear dejected, hopeless, self-abnegating, and pessimistic. They view themselves as helpless to improve their situation in life and do not believe other people can improve it either, thus leading to having little motivation to improve life circumstances and no excitement about the future. Such individuals often neglect themselves in key areas, including hygiene, appearance, employment, and nutrition. They may also struggle with episodes of major depression on top of their overall depressive presentation.

One of the concerns regarding depressive personality is its overlap with dysthymic disorder. For many years, it was commonly thought that depressive personality and dysthymia were one and the same. However, research has found that there are distinct differences between the two, the foremost being that dysthymia, along with major depressive disorder, are most often diagnosed by changes in somatic functioning and a persistent depressive

mood. A person with depressive personality may not report feeling continually depressed. Individuals with depressive disorder only, as compared to those diagnosed with dysthymia only, have significantly higher rates of specific phobias, social phobias, obsessive-compulsive disorder, and generalized anxiety disorder. Those with depressive personality are also twice as likely to be diagnosed with a personality disorder, particularly schizoid, avoidant, dependent, and obsessive-compulsive personality disorders. Additionally, they exhibit greater impaired global functioning, higher rates of suicidality, greater likelihood of past suicide attempts, and greater depressive symptomatology as compared to individuals with dysthymia only. Although depressive personality's comorbidity with both dysthymia and major depression ranges, the personality itself is not subsumed under either of the mood disorders and the rates of people with both depressive personality and dysthymia or major depressive disorder is no higher than the rates for people with other personality disorders and dysthymia or major depressive disorder.

Many orientations have studied the origins and presentation of long-term depression. Although they differ in terms of conceptualizing chronic depression as a standalone disorder or one end of a depressive spectrum, all have found elements of cognitive-interpersonal attributes, including being self-denigrating, melancholy, and sensitive to rejection. Psychoanalytic and psychodynamic theorists posited problems at the oral stage of psychosexual development or a poorly integrated ego. They also examined internalized aggression that turns into depression and regression to states of helplessness. Attachment theory speculated that vulnerability to threatened loss develops either through empathic breaches or misattuned responses between mother and infant. Self-psychology hypothesized that insufficient self-cohesion results in the individual feeling empty and devitalized (Silverstein, 2007). Other environmental factors include lack of familial or social support, loss of parental figures, and parental criticism (Huprich, 2012).

Prevalence

Depressive personality is the most commonly occurring personality prototype identified by practicing clinicians (Huprich, 2012; Klein & Shih, 1998). It has been observed and studied across several ethnic groups, including Caucasian, Asian American, and African American samples. The prevalence for depressive personality is as high as 22% in outpatient and inpatient populations and many clinicians noted difficulty differentiating low-level chronic depression from residual symptoms of a major depressive episode (Bagby, Watson, & Ryder, 2013; McDermut et al., 2003). Depressive personality occurs more often in women as compared to men.

Psychiatric History

Research has found that individuals with depressive personality have an increased current and lifetime risk for major depressive disorder, dysthymic disorder, specific phobias, social phobia, panic disorder with agoraphobia, posttraumatic stress disorder, generalized anxiety disorder, and eating disorders (Huprich, 2012; McDermut et al., 2003). However, they are less

likely to be diagnosed with adjustment disorders than individuals without depressive personality (McDermut et al., 2003). Individuals with depressive personality also demonstrate higher rates of all personality disorders except for antisocial personality disorder, particularly with avoidant, borderline, and obsessive-compulsive personality disorders (Huprich, 2012; Klein & Shih, 1998; McDermut et al., 2003). Other findings associated with depressive personality include higher levels of suicidality, higher level of comorbidity with both mental disorders and personality disorders (previously known as Axis I and II disorders), decreased social functioning, and increased unemployment rates (McDermut et al., 2003).

Familial/Biological Factors

First-degree relatives of people with depressive personality are more likely to have a history of any psychiatric disorder, specifically depression, bipolar disorder, alcohol abuse, and antisocial personality disorder (Huprich, 2012; McDermut et al., 2003). They also have higher rates of major depression and depressive personality as compared to first-degree relatives of individuals without depressive personality. First-degree relatives have a higher risk of developing psychiatric disorders, particularly bipolar disorder, depression, and antisocial personality disorder. There has also been a study that reported structural differences in the genu and posterior midbody of the corpus callosum of female patients diagnosed with depressive personality (Huprich, 2012).

Treatment Implications

Overall, depressive personality has been associated with a slower rate of recovery and lower rates of remission. It usually does not respond well to psychotropic medication, although it may alleviate depressive symptoms from a major depressive or dysthymic episode. Individuals with depressive personality also exhibit greater baseline severity pre-treatment and more depressive symptoms post-treatment as compared to individuals who do not have depressive personality.

Cognitive behavioral therapy (CBT) is an effective treatment for depressive disorders and has been found useful with those who have depressive personality. It can teach an individual how to examine pessimistic cognitions, examine developmental patterns that contribute to those cognitions, identify sources of pleasure and the potential for social enhancement, and undertake positive activities through behavioral activation. Psychodynamic therapy has also been found useful, particularly with prior research postulating that depressive personality may have roots in attachment disturbances. However, interpersonal therapy has significantly poorer remission rates as compared to other modalities (Maddux & Johansson, 2014).

Future Directions

Prospective research into depressive personality would benefit from several considerations. Continued research into the differences between dysthymia and depressive personality at the cognitive, biological, emotional, and developmental levels would clarify whether depressive personality is indeed on the low end of a depressive disorders spectrum or

whether it is a distinct personality type that is more vulnerable to major depression and dysthymia. Future research would benefit from twin and family studies to explore the potential biological marker in the genu and corpus callosum. Finally, research into therapeutic and psychopharmacologic interventions with individuals who have depressive personality would assist clinicians in developing appropriate treatment plans, allowing for increased improvement rates and less attrition from therapy.

Dissociative Disorders

Steven Jay Lynn[1], Craig P. Polizzi[1], and Scott O. Lilienfeld[2]

[1] *Binghamton University*
[2] *Emory University and University of Melbourne*

Dissociative disorders have sparked debate for more than a century. Nevertheless, researchers have made substantial strides in determining their nature and potential antecedents, and theorists have proposed promising but competing accounts of their etiology.

Dissociative Disorders and Dissociative Experiences

Dissociative disorders are marked by discontinuities in the "normal integration of consciousness, memory, identity, emotion, perception, body representation, motor control, and behavior" (American Psychiatric Association, 2013, p. 291). Yet people with a dissociative disorder often vary in more ways than they share a uniform symptom profile. Some experience radical alterations in their sense of self and their surroundings, others experience difficulties in their recall of events, and still others experience profound alterations in their sense of identity and abrupt changes in emotions.

The DSM-V provides the following guidelines for diagnosing the three major dissociative disorders:

1. *Dissociative amnesia* is diagnosed in the presence of an inability to recall important autobiographical information, typically of a traumatic or stressful nature, that is inconsistent with ordinary forgetting. This disorder typically "consists of localized or selective amnesia for a specific event or events, or generalized amnesia for identity and life history" (American Psychiatric Association, 2013, p. 298).
2. *Depersonalization/derealization disorder*, formerly known as depersonalization disorder, is diagnosed based on persistent depersonalization, derealization, or both. Depersonalization symptoms include (1) experiences of unreality; (2) feelings of detachment or being an outside observer of one's thoughts, feelings, sensations, or actions; (3) an unreal or absent sense of self; (4) intense physical and emotional numbing; and

(5) marked time distortion. Derealization involves feelings of unreality or detachment with respect to one's surroundings that include the experience of individuals or objects as unreal, dreamlike, foggy, visually distorted, or lifeless.

3. *Dissociative identity disorder,* formerly known as multiple personality disorder, is diagnosed when evidence exists of a striking disruption of identity distinguished by two or more separate personality states and recurrent gaps in the recall of everyday events, personal information, and/or traumatic events that are inconsistent with ordinary forgetting (American Psychiatric Association, 2013, p. 292).

To merit a diagnosis, dissociative disorders must (a) interfere with important areas of daily functioning (e.g. academic, interpersonal, occupational); (b) elicit subjective distress; and (c) not be the product of a substance or another medical condition.

Prevalence of Dissociative Disorders

Estimates of dissociative disorder lifetime prevalence vary widely and range from 0.3% in the general population to as high as 18.3% for lifetime dissociative disorder diagnoses in a Turkish female sample (Lynn et al., 2014). Rates of dissociative disorders tend to be much higher in clinical populations, but variability is still the norm, with rates ranging from 12–17% to 28–40.9% lifetime prevalence in inpatient settings to as high as 34.9% in a psychiatric emergency facility (see Lynn et al., 2014). Some studies report a greater prevalence in females; others report no differences. Potential reasons for the disparities in rates include differences in assessment instruments, base rates at different facilities, referral and selection biases (females with dissociative disorders may more often end up in psychiatric settings; males may more often end up in forensic settings), and co-occurring symptoms and potential examiner bias (Lilienfeld & Lynn, 2015).

Dissociative Amnesia

DA is highly controversial: Where, if anywhere, to draw the line between "ordinary forgetting" and more extensive memory deficits is not clear. Although the diagnosis precludes cases of memory loss attributable to a substance or a neurological condition (e.g. traumatic brain injury, seizures), it is often impossible to rule out such antecedents. Additionally, reports of extensive forgetting could be attributable to malingering, or to reluctance or unwillingness to think about or report distressing or embarrassing events. Although DA is said to often occur in response to a traumatic event, the experience of trauma typically produces *opposite* effects on memory: traumatic memories are generally salient, highly memorable, and not readily forgotten. Such concerns have prompted questions regarding the existence of DA as a valid diagnostic entity.

Prevalence, co-morbidity, *and presentation*. Estimates of the prevalence of the diagnosis vary widely among the general population across cultures: 0.2% in China, 0.9% and 7.3% in Turkey, and 3.0% in Canada (Dell, 2009). In addition to differences in diagnostic thresholds, variability may reflect actual cultural differences in the disorder.

The presentation of DA is also highly variable. Episodes can vary from minutes to many years; they can be an isolated event or recur. DA is most likely to occur between the ages of 30 and 40, last between one and five days, and emerge equally among both sexes (American Psychiatric Association, 2013).

Depersonalization/Derealization Disorder

Depersonalization/Derealization Disorder (DDD) is the most common and least controversial of the dissociative disorders. In DDD, reality testing remains intact and individuals know they are not experiencing a true break with reality (American Psychiatric Association, 2013, p. 302). Depersonalization and derealization can evoke distress, even to the point of fear of dying, or, rarely, developing psychotic symptoms.

Diagnostic considerations. Single episodes of DDD are common; as many as half of adults report at least one such episode in their lifetimes (Aderibigbe, Bloch, & Walker, 2001). Accordingly, DDD is diagnosed when symptoms are persistent, occur at least once a month, are disturbing and/or interfere with daily functions, and cannot be better accounted for by another disorder. The onset of DDD can be can gradual or abrupt; the disorder can be chronic or episodic and vary from hours to years, and even, in extreme cases, persist for decades. Episodes can be triggered by intense stress and are anxiety-eliciting social interactions; panic attacks; posttraumatic stress disorder; hallucinogenic drug intake, depression; and a history of abuse, parent rejection, and punishment (see Lynn et al., 2016).

Prevalence and co-morbidity. The annual prevalence of a single episode of DDD is estimated to be 23% (Aderibigbe, Bloch, & Walker, 2001), with a lifetime prevalence between 26% and 74%. Lifetime prevalence of DDD is estimated at 2% with a range of 0.8% to 2.8% (American Psychiatric Association, 2013; Lynn et al., 2016). DDD diagnosis rates are approximately equal in females and males). The rate of DDD ranges as high as 16% in inpatient samples (Hunter, Sierra, & David 2004). DDD frequently occurs in the presence of anxiety disorders, particularly panic disorder; major depression; personality disorders (e.g. avoidant, borderline, obsessive-compulsive); somatoform disorders; substance use disorders; and acute stress disorder (see Lynn et al., 2016).

Dissociative Identity Disorder

DSM-V defines DID as "the presence of two or more distinct personality states or experiences of possession" (American Psychiatric Association, 2013, p. 292). The terms "identities" and "personalities" are used herein because they encompass "personality states" and are widely represented in the DID literature (see also Lynn et al., 2014). A diagnosis is possible when personality changes are "observed by others" or "reported by the individual" (American Psychiatric Association, 2013, p. 292) and when "sudden alterations or discontinuities in sense of self or agency and recurrent dissociative amnesias" are manifested (American Psychiatric Association, 2013, p. 293). A diagnosis is appropriate when the identity disruption is not a typical or acceptable part of a person's culture or religion.

DID symptoms are highly variable across individuals; they can be episodic or continuous, and DSM-V specifies numerous indicators of personality shifts, such as changes in

attitudes, food preferences, perception one's body is of the opposite gender, and perceptions of internal voices. Identities can purportedly range from 2 to more than 100, although rare cases have reportedly involved up to 4,500 alters, a number that strikes many critics of the diagnosis as implausible.

Prevalence and co-morbidity. General population prevalence rates for DID in Turkey, Canada, and North America are all estimated to be approximately 1%, with similar rates for men and women (Lynn et al., 2016; American Psychiatric Association, 2013). In clinical samples, prevalence rates typically exceed 10% (see Lynn et al., 2016). Females are three to nine times more likely to be diagnosed with DID in clinical settings; however, selection and referral biases may account for gender disparity.

DID is a transdiagnostic set of signs and symptoms that may reflect severe psychopathology, negative emotionality, or both. Ellason, Ross, and Fuchs (1996) reported that individuals diagnosed with DID also met criteria for 8 Axis I (major) disorders and 4.5 Axis II (personality) disorders, on average. Individuals with DID often report severe symptoms, including self-mutilation, suicidal or aggressive behavior, and sexual and eating dysfunctions. DID and dissociative symptoms more generally also co-occur with schizoaffective disorder, bipolar disorder, borderline and other personality disorders (e.g. schizotypal, avoidant, histrionic), anxiety disorders, obsessive-compulsive disorder, substance use disorders, depression, and posttraumatic stress disorder (see Lynn et al., 2014).

Theories of Dissociation

The trauma model of dissociation. The trauma model (TM) and the sociocognitive model (SM) have dominated contemporary accounts of dissociation and dissociative disorders. The TM argues that dissociation, particularly severe dissociation that marks DID, can be traced to a childhood history of severe physical or sexual abuse, or severe stressors later in life. Proponents of this view contend that dissociation serves a defensive function, with alter personalities arising to wall off memories and the emotional residues of abuse to cope with the psychic pain of the trauma (see Dalenberg et al., 2012; Gleaves, 1996). Different personality parts/alters thus ostensibly come about to manage different aspects of the trauma. For example, from this perspective, an angry or a protector alter might emerge when incipient memories or emotions associated with the original traumatic event are triggered.

TM theory is supported by apparently high rates of trauma, sometimes in excess of 90%, in association with DID (Dalenberg et al., 2012). Nevertheless, critics of the TM (e.g. Giesbrecht et al., 2008) have observed that the correlation between a history of abuse and dissociation is highly variable across clinical and nonclinical samples, ranging from $r = -.14$ to $r = .63$ (Dalenberg et al., 2012). Moreover, corroboration of abuse is often lacking, most studies rely exclusively on self-reported trauma, and studies that follow participants over time often fail to find a significant correlation between early abuse and adult dissociation. Furthermore, dissociative symptoms are present in many disorders, and a history of child abuse is frequently reported in the context of many disorders, rendering the specificity of the link between dissociation and child abuse suspect.

Contrary to the view that trauma is central to dissociation, the SCM holds that social, cultural, and cognitive variables combine to foster a credible personal narrative of multiple selves. These variables include (a) widely held cultural beliefs about the link between abuse

and dissociation, often propagated by media accounts in books, movies (e.g. *Sybil*, *The Three Faces of Eve*, *Split*), and television programs (e.g. *United States of Tara*); (b) inappropriately suggestive techniques in psychotherapy (e.g. hypnosis to recover memories, calling alters by names, pressing for recall of abuse after denials of abuse) to unearth supposedly dissociated or repressed memories of abuse and that imply that puzzling and/or rapidly shifting thoughts, emotions, and behaviors are the products of multiple indwelling entities; (c) fantasy-proneness, which may engender inaccurate reports of childhood trauma; and (d) high suggestibility, which increases vulnerability to false memories. Consistent with the SCM, laboratory evidence (e.g. event-related potentials, behavioral tasks) does not support the notion that DID is characterized by independent personalities separated by unbreachable amnesic barriers (Huntjens, Verschuere, & McNally, 2012).

The SCM, like the TM, has not escaped criticism. Adherents of the TM have argued that suggestion, suggestibility, and fantasy-proneness are not sufficient to provide a comprehensive account of dissociation, as none of the correlations of these variables with dissociation exceeds $r = .40$ by much on a consistent basis. Nevertheless, it is unclear whether this rebuttal is compelling given that the SCM views these individual differences as vulnerability, not as determinative, factors.

Researchers and theorists have identified other variables that could contribute to understanding dissociation. For example, sleep disturbances may promote entry of dreamlike cognition into waking life that engenders feelings of depersonalization/derealization. Depriving participants of sleep increases dissociative symptoms, whereas sleep hygiene to promote undisturbed sleep decreases dissociative symptoms (see Van der Kloet et al., 2012), implying a potential causal relation between sleep and dissociation. Moreover, high scorers on dissociation exhibit (a) failures in self-regulation and executive control, alongside a tendency to hyperassociate and shift mental sets in the face of arousing or negative stimuli; and (b) difficulties in monitoring, identifying, and elaborating their thoughts, feelings, and action tendencies, all of which promote failures in integration of diverse elements of experience (Lynn et al., 2016).

Finally, researchers have identified genetic and other potential biological pathways to dissociation. Inconsistent yet generally positive evidence exists for a genetic substrate of dissociation, with between 48% and 59% of variability in measures of dissociation attributable to genetic influences (see Lynn et al., 2016). Moreover, an altered sense of reality and the self in DDD are associated with a mismatch between (or a failure to integrate) multisensory inputs (e.g. visual, proprioceptive, vestibular) and that DDD occurs in conjunction with activation of the right dorsolateral prefrontal cortex while the anterior cingulate is inhibited reciprocally (Lynn et al., 2016). Other neurobiological models of dissociation consider the impact of default mode mediation of self-referential processing, overmodulation and undermodulation of affective states, inter-hemispheric communication, and neural networks.

Conclusions

Competing theories of dissociation and dissociative disorders have been advanced to account for individual differences in dissociation. Multifactorial perspectives, which consider early trauma, sociocognitive, neurobiological, and genetic variables, will be necessary to provide a comprehensive etiological narrative of the expression of dissociation in its myriad manifestations.

Features and Diagnosis

Autism spectrum disorder (ASD) is defined in the current Diagnostic and Statistical Manual of Mental Disorders of the American Psychiatric Association (DSM-5; American Psychiatric Association, 2013) primarily by deficits in two domains: social interaction and communication, and patterns of preferred activities, behaviors, and interests. These include difficulties in conducting regular conversation between peers, understanding and using nonverbal communication, and in developing relationships. Individuals with ASD also tend to show unusual sensitivity to changes in their regular, preferred social or material environments and routines, as well as idiosyncratically fixated interests or attachment to specific objects. These impairments typically are evident and stable from early in life, but vary widely in focus and severity across individuals. The early emergence of most common manifestations of ASD point to basic neurobiological variations of likely genetic origin; however, the variety of behavioral features, and their typical influences on achieving common developmental milestones, has led researchers and practitioners to conceptualize traits of autism along a spectrum.

Swiss psychiatrist Eugen Bleuler first used the term *autism* in the early twentieth century to describe symptoms of extreme self-focus that he and his predecessors had observed among children with bizarre behavior, which he and others likened to schizophrenia. Austrian pediatrician Hans Asperger, and Austrian immigrant to the United States psychiatrist Leo Kanner, are credited with using the term beginning in the 1940s to describe childhood cases of impaired social interaction, idiosyncratic behavior, and restricted communication as a clinically distinct pattern (Volkmar & McPartland, 2014). Systematic observations and descriptions by Mark Rutter and by Lorna Wing promoted formal diagnostic classification of significant patterns associated with autism in the United States. Through 2000, autism was presented as one among several "pervasive developmental disorders" (PDDs), alongside Asperger's disorder, childhood disintegrative disorder, and "pervasive developmental disorder not otherwise specified." Beyond heterogeneity in the

behavioral manifestations and their severity among individuals specifically with "autistic disorder," overlap among the four supposedly distinct PDD categories, as well as clinicians' inconsistency in applying subtle differential diagnostic criteria, reinforced the practicality of a spectrum approach to the disorder. Ultimately, these challenges led to combining these diverse patterns into the one comprehensive diagnosis of ASDs, in the current (2013) edition of the DSM.

Prevalence and Incidence

ASD affects approximately 1 in 59 children in the United States, nearly five times more prevalent among boys than girls. Prevalence estimates have increased dramatically in recent years, up from only 1 in 150 as late as 2000. No comprehensive, direct explanations for these increases have been identified, although multiple likely contributors include growing public and professional awareness of ASD and its symptoms, and greater availability of assessment and treatment services. While the possibility of *actual* increases in ASD incidence remains under investigation, systematic research has ruled out some postnatal environmental factors suspected as causal, such as childhood immunizations. Epidemiological research suggests lower but similar prevalence rates outside of the United States and Europe; however, limited research, with open questions of cross-cultural validity, present ongoing challenges to generalizing findings beyond these regions.

Related Personality Characteristics

Consistent with the spectrum approach, research has identified milder but consistent trait-like patterns characteristic of autism in wider, nonclinical populations. These patterns, originally studied in families and siblings of individuals with autism, have been labeled the *broader autism phenotype* (BAP). The BAP describes marked tendencies toward atypically low levels of social interest and enjoyment, difficulties adapting to altered routines, and associated dysfluencies in language and social skills. Individuals with characteristics of the BAP do not necessarily meet criteria for a clinical ASD diagnosis; however, the BAP has been shown relevant to personal and interpersonal adjustment, associated with factors such as limited social-cognitive abilities, loneliness, and unsatisfying friendship quality and duration. The continuum of characteristics from BAP through fully diagnosable ASDs thus appear to influence an associated range of mental health outcomes.

Descriptive approaches to autism spectrum disorders and the BAP suggest common patterns of psychological characteristics that differ chiefly in severity. Contemporary dimensional approaches to normal personality and its disorders have been invoked to characterize these patterns empirically. Research using the Five Factor Model (FFM) conceptualization of personality has suggested that adults on the autism spectrum show lower characteristic extraversion (sociability and tendency to seek stimulation through interaction with others), and openness to new experiences, as well as stronger tendencies toward neuroticism

(negative affectivity), compulsiveness, and inhibition (Schwartzman, Wood, & Kapp, 2015). Similarly, studies of the BAP among parents and relatives of children with autism suggest that the FFM dimensions and facets can characterize their low extraversion and social disengagement. Besides these, the social and interpersonal components of the BAP also correlate with Neuroticism, particularly regarding proneness to experience emotional vulnerability and anxiety, which in turn are associated with adverse reactions to stress and lower well-being. Furthermore, recognized facets of the FFM factors have been used to characterize subtypes of adult ASD patterns, explaining even more variance in symptomatology. These associations underscore both the role of the BAP within the larger spectrum of autism-related characteristics and the utility of models of basic personality to characterize the continuum of key traits and behaviors across general and clinical populations.

Cultural and Demographic Matters

The epidemiology of autism has been investigated most extensively in Euro American populations, such as within the United States, while limited evidence of cross-cultural instrument validity and inconsistent methods constrain firm conclusions about global prevalence, incidence, and risk. Still, populations around the world have recognized ASD as a legitimate condition, and increasing awareness has prompted more epidemiological investigations to illuminate how socio-cultural factors may influence assessment, diagnosis, and interventions for ASD. Key diagnostic features of ASD potentially influenced by socio-cultural norms include expected reciprocity in social interactions, affective experience and expression customs, normative levels of eye contact, and cognitive rigidity. These also may include expected behavior by gender, which may contribute to the imbalanced sex ratio in diagnosis. Group-specific modifications of diagnostic and treatment techniques have sought to increase sensitivity to these nuances. Other considerations have involved attention to the cultural contexts of treatment, including how families and communities understand ASD as a disorder, and their decisions to pursue diagnosis and treatment. Culture and ethnic background also influence awareness and access to ASD-related information and resources, traditions and practices for helpseeking, and stigma associated with ASD-related characteristics.

Research on culturally appropriate assessment of ASD has focused mainly on linguistic adaptations of ASD measures for different countries. The Social Responsiveness Scale (SRS), Autism Spectrum Quotient (AQ), and the Modified Checklist for Autism in Toddlers (M-CHAT) are among the instruments that have been adapted for specific contexts, including China and Turkey. Modifications of these measures have included wording changes to reflect cultural nuances in describing ASD symptoms, colloquial expressions, as well as relevant religious or other community-based values. While linguistic translation is the most basic level of adapting measures for cross-cultural use, growing demand to evaluate autism across cultural contexts is encouraging more sophisticated investigation of conceptual equivalence and validity of assessment methods. Effective cultural adaptations, in turn, likely will influence conceptualizations of ASD symptoms and refine understanding of underlying etiology.

Theories and Controversies

Early-twentieth-century theorists considered autism as a form of childhood schizophrenia. Influenced by psychoanalytic paradigms, early etiological theories considered characteristics such as idiosyncratic inward focus and odd responses to the environment as emblematic of profoundly emotionally distant parenting. These views became increasing unlikely, however, with mounting evidence of the early appearance – diagnosable in some cases as early as 14 months of age – of symptoms, and absence of relationship with actual observed parenting patterns. While Kanner's seminal work in the 1940s did conclude that a pathogenic lack of parental warmth contributed to the development of autism, consistent with psychoanalytic theories of the time, he nonetheless framed the disorder as an outcome mainly among biologically sensitive children. By the middle of the twentieth century, mainstream psychiatric approaches emphasized Kanner's conceptualization of the likely biological roots of autism.

In the 1970s, child psychiatrist and temperament researcher Stella Chess described rubella as a significant potential neurological risk for autism, pioneering current research emphases on specific neurodevelopmental mechanisms. Careful observational approaches also helped rule out speculation that childhood immunization and other toxicological factors cause ASD. Current etiological theories focus on atypical development of key neurological pathways, as well as other genetic vulnerabilities potentiated by prenatal and perinatal risks.

Family studies point to genetic contributions. Monozygotic twins show significantly higher concordance rates of autism spectrum disorders than dizygotic twins or singleton siblings; however, other factors must be operative since these concordance rates tend to be far less than 100%. Furthermore, an array of genetic syndromes has been linked empirically to autism spectrum disorders in varying degrees; Fragile X syndrome is a notable example. Each genetic variation may influence specific mechanisms related to behavioral manifestations of ASD, from sensory processing and receptive or expressive communication capabilities, to emotion recognition and reward processing. Early disruptions in any of these neurobiological systems also may exert indirect influence by interrupting critical early environmental experiences that lay foundations for later typical interpersonal learning and development.

The heterogeneity of symptom presentation in ASD has reinforced the importance of descriptive precision and personality research – including the BAP – to help explore and categorize causal pathways. While ASD diagnostic tools tend to be more precise among infants and children, personality approaches to ASD offer meaningful coherence regarding behavior patterns observed among adults, as well as clues about common underlying biological substrates. These behavior patterns can be considered phenotypes reflecting underlying relatively stable traits. To the extent that adults' psychological characteristics also have their origin in biologically determined response tendencies, studies investigating basic temperament – as precursors and building blocks of basic personality – have suggested some patterns among infants at risk. Approaches to temperament also lend themselves to dimensional characterization, yielding patterns like those seen in personality research. Caregiver reports and experimental observations have shown that infants and children on the autism spectrum have difficulties regulating their responses to the environment. These include being harder to soothe (suggestive of the negative affectivity facets of

neuroticism), characteristic problems controlling attention (suggestive of facets of conscientiousness observed among adolescent and adult personalities) and notably lower sociability and social interaction initiation (as suggested by lower facet scores of openness, extraversion, and agreeableness evident in adult self-reports). Importantly, these patterns also distinguish infants on the autism spectrum from those with other neurodevelopmental disorders, such as Down syndrome.

The wide range of ASD symptom presentations (such as restricted communication capabilities) and comorbid conditions (including intellectual disability) also confound assessment methods and differential diagnosis. Self-report methods, including reliance on retrospective caregiver reports of infant behavior, complicate the persistent problems of ASD diagnosis. Conceptually, overlap between ASD and temperament/personality may grow out of common roots, simply represent similar biological mechanisms, or reflect different phenomena mediated by shared third variables, such as culture-specific conceptualizations or even artifacts of the models and measures of personality invoked.

Interventions

Consistent with findings linking early temperament and its progression into adult personality traits, early interventions have strong associations with increased positive outcomes for adults with ASD. Empirically supported interventions for ASD tend to focus on learning skills to target specific dysfunctional behavior patterns that may undermine adjustment in school, employment, or meaningful relationships (Bishop-Fitzpatrick, Minshew, & Eack, 2013). Among the most successful and comprehensive systems is applied behavior analysis, which employs basic conditioning principles selectively and intensively to prompt, reinforce, and practice targeted desirable behaviors (such as socially appropriate eye contact, and functional communication skills), and extinguish undesirable ones (such as stereotyped self-stimulation or verbal perseveration). Other intervention approaches also feature learning and reinforcement techniques to help individuals with ASD acquire appropriate and useful behavioral repertoires, particularly as facilitated individually or in small groups. Effective interventions with adults, particularly those considered "higher functioning" with respect to their ASD symptoms, also have included computer-based social cognition training aimed at helping them better understand social cues, and therefore respond more effectively (Wong et al., 2015). Systematic reviews of outcome evidence suggest that children and adults treated in these ways tend to demonstrate and maintain functional gains.

No pharmacological interventions treat ASD directly, but often are used in individual cases to target comorbid symptom patterns, such as attentional or anxiety disorder problems.

Substance Use Disorders and Behavioral Addiction in the DSM-V

Addiction in general describes patterns of maladaptive behavior associated with short-term reward, as well as adverse consequences related to excessive use and poor control over these behaviors. The American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) classifies these forms of psychopathology together in the category "Substance-related and Addictive Disorders," based on key similarities in etiology and behavioral symptoms across substance use and gambling disorders. *Substance-related disorders* are broken down according to impaired control over the use of 10 classes of drugs: alcohol, opioids, stimulants, sedatives, hypnotics, anxiolytics, hallucinogens, cannabis, inhalants, and caffeine. *Gambling disorder* is the only formal classification of behavioral addiction in the DSM-V, although emerging research points to the potential to add other maladaptive behaviors including gaming, internet use, and social network disorders, and sex and exercise addictions.

Other studies point to the addictive nature of eating pathology, including restriction, overeating, and compensatory behaviors against weight change. Research has suggested shared components across these diverse forms of addictive behaviors: dominance of the behavior across life domains, affect-modifying effects of engaging in these patterns, tolerance, withdrawal symptoms, relapse patterns, and tendencies to cause intrapsychic and interpersonal conflicts.

The conceptualization and classification of substance-related and behavioral addictions have moved from a binary diagnostic decision to a continuum describing psychological dysfunctions in the DSM-5. Not only does a continuum perspective help contextualize the high rates of comorbidity among behavioral addictions and substance use disorders, these changes also reflect ample scientific knowledge suggesting common underlying etiologic

and prognostic factors, including genetic predisposition, dysregulation in the brain reward system, and personality vulnerabilities.

Addictive Personality

In the early twentieth century, mental health professionals began to invoke personality as an explanation for maladaptive substance use patterns. These professionals were trained primarily in psychoanalytic orientations. Hungarian-born psychiatrist Sandor Radó is perhaps most closely associated with articulating the original framework of addictive personality. Radó conceptualized substance addiction as the result of a regularized pattern of responses to intrapsychic forces generating the impulse to use drugs. He criticized mainstream psychiatry of the time for misattributing the social problems and distress associated with substance abuse to the toxic effects of the drugs themselves. He argued that the causes, common patterns of maladaptive behavior, and pathways for intervention lay in understanding the shared deep structure of psychological characteristics leading to substance use, rather than substance use leading to intrapsychic problems. Building on Sigmund Freud's psychoanalytic formulation of dysfunctional behavior, Radó argued that the search to recreate "primitive," all-encompassing sensual gratification of infancy leads individuals into cycles of self-focused pleasure seeking that come to surpass other more "mature" – and less socially and self-destructive – satisfactions. Reflecting the primitive character of these urges, persons with addictions often use similarly primitive defense mechanisms, such as denial and deception, when confronted by others about their dysfunction. Addiction therefore could be considered a psychological problem because cravings for the drug of choice represent desperate attempts to cope with an environment that does not offer lasting relief for the psychological suffering that these individuals experience. Drug seeking becomes part of a characteristic cycle of attempts to recreate the inevitably short-lived pleasurable experience, as well as to avoid the loss of self-regard from failing to use more socially acceptable coping.

This psychodynamic conceptualization of addictive personality thus characterizes it as a narcissistic (extremely self-focused, marked by high levels of disagreeableness) or antisocial (including rebelliousness, lack of social responsibility, and impairment in judgment) disorder. Although psychoactive effects of substances differ, all forms of substance misuse serve the primary, infantile search to generate pleasure, and minimize or avoid suffering. As a dominant influence on the organization of the first DSM and subsequent DSM-II, attention to such psychodynamic mechanisms led to classifying alcohol and other substance use disorders under the category of "Personality Disorders and Certain Other Non-Psychotic Mental Disorders." Psychodynamic theory supporting the first two DSM editions highlighted observations that antisocial and narcissistic personality characteristics are particularly reliable in differentiating those with and without "alcoholism" or other "drug addiction."

Whereas attributing all forms of addiction to a single personality pattern has faded in popularity in light of growing evidence for alternative explanations that are based on a mix of characterologic factors, the exploration of the addictive personality was important for advancing the notion that stable characteristics, experiences, and coping contribute to substance and behavioral addictions.

Personality Vulnerabilities Across Substance Use Disorders, Behavioral Addiction, and Eating Disorders

Cross-sectional patterns and systematic studies of personality characteristics provide a solid evidence base for understanding their roles in addictive disorders. Longitudinal studies have shown that parents with a lifetime diagnosis of substance use disorders are at greater risk for having offspring with temperament disturbances during infancy. Infants' "difficult temperament" is associated with lower levels of easiness and thresholds for arousal, greater distractibility, irregularity of daily routines, and negative reactions to novel experiences in childhood. These characteristics suggest an etiologic factor underlying the substance use diagnoses in the DSM (see Kotov, Gamez, Schmidt, & Watson, 2010). The fact that substance use among parents and early childhood characteristics can predict individuals' substance use disorder diagnoses in adulthood provides robust evidence of shared biological predispositions across personality traits and addictive behaviors.

Impulsivity

Impulsivity is among the most studied predictors of substance misuse. Greater impulsivity is associated with earlier onset of addiction and more severe adverse consequences (Sharma, Markon, & Clark, 2014). Family-tree interviews and behavior genetic studies have indicated that the density of relatives with substance use disorders is higher among drug users with high level of impulsivity. Furthermore, less impulse control – associated with earlier onset of puberty – has shown to predict greater frequency and quantity of substance use among adolescents. Among individuals with cocaine use disorders, gambling disorder, and food addiction, those with higher levels of trait impulsivity and poorer executive functioning tend to report poorer psychosocial functioning and quality of life, and show worse clinical outcomes than those with lower levels of impulsivity.

Traditionally, impulsivity referred to behaviors performed with little or inadequate premeditation. More recently, impulsivity has been conceptualized in terms of four trait components: sensation seeking (negative and positive), urgency, disinhibition, and lack of perseverance. Sensation seeking reflects extraversion and positive affectivity. Urgency is the tendency to act in an intense emotional state. Disinhibition points to low level of deliberation and cautiousness. Lack of perseverance indicates resourcelessness and poor self-discipline.

Among the four impulsivity components, negative urgency (i.e. the tendency to act rashly while in a distressed state) plays a central role in alcohol, drug, and cigarette use, and gambling behavior, whereas disinhibitory tendency is shown to be the second most robust contributor. By comparison, sensation seeking and lack of perseverance are less predictive of substance and behavioral addictions. Furthermore, negative and positive urgency, as well as lack of perseverance, not only are associated with greater food addiction but also in turn predict higher body mass index. Other studies have indicated that self-reported tendency to use addictive behavior to alleviate negative emotions further amplify the impact of urgency-related impulsivity, which then is predictive of bulimia nervosa diagnosis.

Novelty, Sensation, and Excitement Seeking

Novelty seeking and sensation seeking reflect a similar underlying individual trait that is assessed by different instruments. Both denote the tendency to pursue intense excitement in the presence of novel stimuli that elicit reward or relief from aversion. Excitement seeking in the Big Five nomological network is indicative of extraversion and positive affectivity. Broader measurements of this construct have shown a positive correlation with extraversion and a negative correlation with conscientiousness. In general, sensation seeking has been found to be the lowest among non-substance users, and higher among alcohol users, cannabis users, and illicit drug users, in increasing order. Sensation seeking partially mediates the relations between early puberty status and adolescent substance use, even when impulse control is controlled.

Big Five Personality Traits

The Big Five nomological network of basic personality traits has contributed to a considerable body of research on addiction tendencies. Neuroticism is characterized by emotional (in)stability and tendency to experience negative affect and experiences. Extraversion refers to the breadth of positive affect and affinity to energy from external sources. Openness indicates an interest and appreciation for diverse experiences and ideas. Agreeableness reflects general concern for others and interpersonal harmony. Conscientiousness is characterized by organization, planfulness, self-discipline, and diligence. The five-factor structure has been helpful in organizing broadband personality traits and describing their impact on addictive behaviors. Among the five personality domains, high levels of extraversion and neuroticism, and low level of conscientiousness/constraint have been shown to predict more addictive behaviors.

When considering the Big Five personality traits simultaneously, high levels of extraversion coupled with low levels of conscientiousness are linked to increasing levels of alcohol consumption over time. Greater neuroticism and agreeableness, and lower levels of openness to novel experiences collectively are predictive of decrease in drinking over time from moderate levels to abstinence.

Extraversion, moderated by high level of expectancies to be social, is predictive of increased alcohol use among college students. High degree of extraversion is associated with greater social networking addiction (e.g. use of social media tools such as Facebook and LinkedIn) but not with general internet-use addiction, whereas low levels of extraversion are predictive of anorexia nervosa symptoms. Extraversion is associated with heavy alcohol consumption and lower likelihood to be abstinent in both cross-sectional and prospective studies. Its relation with addictive behaviors evidently is driven by high levels of sensation seeking and sociability, and social-oriented drinking motives. Neurotic features not only are linked to greater consumption of substances, and internet and social networking addictions, but also predict anorexia nervosa and bulimia nervosa symptomatology. Low levels of conscientiousness are associated with heavy drinking in cross-sectional data, and an increase from moderate to heavy drinking in longitudinal studies.

Variability of Personality Risks Across Addiction Subtypes and Samples

Despite some similarities of psychodynamic patterns or personality "signatures" across addictive behaviors, research has shown meaningful variations as well. The present empirical base on substance and behavioral addiction tends to focus on specific substances or clusters of behavioral pathology (cf. Flory, Lynam, Milich, Leukefeld, & Clayton, 2002). For example, most studies of personality underpinnings of substance abuse are conducted among those with alcohol use disorder; few studies simultaneously consider individual differences among those with polydrug use disorder, or comorbid substance use and behavioral addictive disorders. A small body of emerging literature has suggested that certain personality traits are uniquely related to alcohol, other substance use, and eating disorders.

The vast majority of research on addiction has centered on alcohol use. Person-centered research has confirmed that alcohol users tend to share similar characteristics, and their personality patterns differ systematically from those who have other comorbid substance use disorders, or nonalcoholic drug users. Compared to their non-substance using counterparts, people with alcohol use disorder are more likely to have high levels of negative and reactive emotional experiences, whereas nonalcoholic substance users are more likely to score low on measures of constraint, traditionalism, and harm avoidance. Whereas polydrug users are described as shy, distrustful, and emotionally unstable, nonalcoholic drug users are particularly low on constraint than individuals who have both alcohol and other substance use disorders. Research has suggested that more socially deviant personality traits are likely predisposing to individuals who abuse illicit drugs without prior involvement with alcohol, a more socially accepted psychoactive substance.

Emerging evidence with community and clinical populations also points to gender differences in the association between personality and addiction. Men with substance use disorders tend to score higher on measures of constraint than their women counterparts, reflecting gender variations in experience and emotion expression.

Extension of Empirical Questions

Research on the relations between personality traits and addiction has helped advance current understanding of characterological vulnerabilities underlying substance use disorders and behavioral addictions. Most importantly, recent studies have shown that the continuum of personality dysfunctions – rather than a discrete constellation of personality traits – is predictive of the occurrence and severity of substance use. The personality–addiction relational patterns also can enhance precision in targeting clinical interventions. For instance, solitary substance users exhibiting high neurotic features might benefit most from therapeutic interventions emphasizing behavioral activation and social skills. Treatments for social users with high levels of extraversion might target skills in developing new and healthy social networks. Realizing the promise of targeting psychosocial treatments to particular patterns of substance and behavioral addictions awaits further empirical investigation of the personality–addiction linkage.

Whereas most research has elucidated the central roles of impulsivity, extraversion, and neuroticism in substance use disorders and pathological behavioral addiction, further work is needed to evaluate their simultaneous importance, and disentangle these relations by examining their respective subcomponents. For example, extraversion has been found to predict addictive behavior in various social contexts, but meta-analytic reviews suggest that it fails to demonstrate predictive validity in substance use and gambling disorders among clinical samples. Impulsivity has been implicated as the primary common personality vulnerability that underlies addictions regardless of DSM diagnoses. The four components of impulsivity reflect diverse narrow-band characteristics, which complicates empirical study of the impact of "general" impulsivity on addictions. Similarly, neuroticism encompasses withdrawal tendencies (depression, anxiety, vulnerability to stress, and self-consciousness) and volatile tendencies (anger hostility and impulsivity/urgency), each of which might relate to substance use in different ways.

Apart from predictions based on broad personality patterns, the current literature also is limited in establishing proximal predictors linking personality traits and addictive behaviors. It is likely that drug/behavior-specific expectancies, emotion regulation and distress tolerance, and meta-emotion mediate the roles of basic personality tendencies on addictions. For instance, disinhibition and low levels of characteristic persistence on psychological and physical tasks may operate via distress intolerance, leading to maladaptive addictive behaviors. Validating risk mechanisms would be especially valuable in generating clinical interventions that target these proximal, social-learning risk factors.

The tradition of examining characteristic patterns (including addictive personality) as vulnerability factors for addictive behavior has overshadowed research on protective personality traits. Some empirical investigations suggest that trait mindfulness, religiosity, and virtues including transcendence and temperance can protect against problematic substance use. For instance, there are small negative associations between trait mindfulness and substance use disorders, and between temperance (self-regulatory abilities) and drinking-related risky behaviors and adverse consequences. Individuals' ability to act with awareness in a nonjudgmental and nonreactive manner particularly is strongly related to lower problematic alcohol use and tobacco use in inpatient clinical samples.

A final limitation of the existing knowledge base on substance use disorders and problematic addictive behavior is the narrow range of demographic characteristics included in many research samples: investigations tend to focus on college students and Whites. Given that college students in emerging adulthood have the highest prevalence of alcohol use and are at increased risk for pathological substance use across life span, the rich empirical evidence on the relations between personality and addiction in this population is well justified and vital. Focusing heavily on this selected group of individuals, however, restricts the ranges of age, social contexts, and frequency and severity of substance and behavioral addiction represented in the literature. In addition, this also likely limits scientific understanding of the ranges and parameters of personality–addiction relations. Studies that use samples whose personality and/or addictive behavior fall in the abnormal range and who are treatment seeking will deepen the present empirical knowledge tremendously. The predominant focus on European White and White American samples is appropriate for understanding common patterns of the impact of personality on addictive behavior within the United States context: Whites have shown the highest prevalence

of substance use disorders, certain eating pathologies, and gambling disorder, relative to their ethnic minority counterparts. Epidemiological evidence is less clear with regard to the prevalence and adverse consequences of these disorders among immigrant and domestic ethnocultural groups of Asian and Hispanic backgrounds. What remains unknown is whether commonly reported patterns are generalizable to other ethnocultural groups, and what cultural differences (e.g. mean levels of personality traits, drinking norms) may affect these relation.

Borderline Personality Disorder

Kenneth N. Levy and Joanna Pantelides

Pennsylvania State University

Introduction

Borderline personality disorder (BPD) is a highly prevalent, chronic, and debilitating disorder characterized by instability in one's sense of self, others, and mood. This instability is expressed as emotional lability, impulsivity, interpersonal dysfunction, angry outbursts, suicidality, and non-suicidal self-injury. Historically, BPD has been thought to be difficult to treat. Those with BPD tend to be high service utilizers, often in a chaotic manner. BPD is frequently comorbid with a number of other psychological disorders, particularly mood, anxiety, PTSD, and substance use disorders. When BPD is comorbid with other disorders, it has negative effects on the clinical course and outcome of those conditions. Regardless of comorbidity, BPD is related to a host of other negative and costly outcomes, including higher rates of physical and mental disability, and significant long-term functional impairment across multiple domains. Given the severity of the symptoms, the high prevalence rates, complex comorbidity, and negative effects of BPD in general and on other disorders, BPD is a major public health concern.

Epidemiology

Recent epidemiological studies suggest that BPD, with prevalence rates between 1–6% in the general population, is more common than schizophrenia, bipolar disorder, and autism combined. Clinical studies have found that 15–20% of outpatients and up to 40% of inpatients are diagnosed with BPD. BPD is often thought to occur more frequently in women than in men. Some studies have found that women account for 75% of the cases of BPD presented to outpatient departments. A number of explanations have been proposed to explain this disparity. Some authors have suggested that gender differences in prevalence rates may be due to gender bias while others have suggested that this discrepancy results from differences in symptom presentation. Women present with dramatic symptoms such as self-injury, while men present with more impulsive and substance-related symptoms.

Other authors have suggested that women are more likely to seek treatment for symptoms related to BPD, whereas men with BPD are more likely to be in substance abuse or mandated treatment programs. However, recent epidemiological studies have found little or no differences in the prevalence of BPD between men and women.

Comorbidity with Other Psychological Disorders

BPD is frequently comorbid with a number of other psychiatric and psychological disorders such as depression, bipolar II, anxiety disorders, eating disorders, substance abuse disorders (SUD), and posttraumatic stress disorder (PTSD). This pattern of comorbidity is often referred to as *complex comorbidity* because of the number of comorbid diagnoses and the pattern that includes both internalizing and externalizing disorders. This comorbidity is especially meaningful in that the presence of BPD negatively affects the course and treatment efficacy for these disorders. Although the negative relationship between BPD and these disorders can be reciprocal, particularly for SUD and PTSD, the relationship tends to be unidirectional with regard to depression, bipolar II, and anxiety disorders. That is, the presence of BPD negatively affects the course and outcome for these disorders *but* several independent longitudinal studies comprising of thousands of patients suggest these disorders tend to have little effect on the course and outcome of BPD. For example, bipolar patients with comorbid BPD are more likely to be unemployed, use more medications, have increased rates of alcohol and substance use disorders, show poorer treatment response, and have significantly worse interepisode functioning. However, in these studies, a comorbid bipolar disorder did not affect the course or outcome for BPD patients. Likewise, a number of large-scale studies have now found that improvements in BPD were often followed by improvements in major depressive disorder but that improvements in major depressive disorder are generally not followed by improvements in BPD.

Clinical Presentation

BPD is a complex and heterogeneous clinical problem characterized by instability in self-image, mood, and interpersonal relationships. This instability manifests itself as impairments in identify, self-direction, empathy, and intimacy. DSM-IV and DSM-V note nine possible criteria for BPD. These include frantic efforts to avoid abandonment, unstable intense relationships, marked persistent identity disturbance, impulsivity, recurrent suicidal threats, gestures, and behaviors, affective instability, chronic feelings of emptiness, intense anger, and transient, stress-related paranoid ideation or dissociation. In order to be diagnosed with BPD, one has to meet any five of the nine criteria. This polythetic approach results in 256 different ways to meet criteria for BPD. Such heterogeneity is characteristic on many DSM disorders. For instance, there are also 256 different ways to meet criteria for major depressive disorder and 636,120 ways to have posttraumatic stress disorder. Nonetheless, BPD is heterogeneous. For instance, one study found 136 different combinations in a sample of 252 patients. The maximum number with the same combination was eight.

Suicidality

The most serious symptoms of BPD are the high rates of non-suicidal self-injury and suicidality. More than 84% of patients with BPD report some history of suicidal behavior, averaging 3.4 lifetime attempts. The rate of completed suicide among individuals with BPD is also very high. A recent meta-analysis found that 8% of over 1,100 patients completed suicide. This rate is not only much higher than the general population but also higher than other psychiatric disorders. For example, other meta-analyses found a suicide rate of 2.3% among over 1,500 patients with anorexia nervosa and 1.3% for unmedicated bipolar disorder. Predictors of suicidality include history of parasuicidality, hospitalizations, younger age, hostility, and impulsivity.

Non-Suicidal Self-Injury (NSSI)

Perhaps the most perplexing symptom of BPD is non-suicidality self-injury. Studies show that 70–75% of those with BPD have engaged in self-injurious behaviors, the most frequent behaviors tending to be cutting, burning, and overdosing. The reasons reported for engaging in NSSI are varied. Some have suggested that those with BPD are less receptive to pain. The evidence is mixed on this, as other studies have found that those with BPD tend to be sensitive to pain, particularly chronic pain syndromes. Other reasons reported for NSSI include combating feelings of dissociation, self-punishment, asserting control over one's behavior, distracting oneself from psychological pain with physical pain, releasing pent-up feelings of anger, guilt, shame, and stress, and to show others how bad they are feeling. Studies indicate that about a third of those with BPD who engage in NSSI begin prior to age 13, a third begin during adolescence, and a third begin in young adulthood. It is rare for those with BPD to begin cutting after their thirties, though it can occur. It is important to note that NSSI increases the risk for suicide attempts and death even in the absence of suicidal ideation. In fact, many patients with BPD accidently kill themselves while engaging in NSSI.

Assessment, Diagnosis, and Misdiagnosis

Despite the consequences of BPD, evidence suggests that clinicians often fail to recognize and diagnose personality disorders in ordinary clinical practice. One study found that 74% of BPD patients had previously been misdiagnosed despite an average of 10 years since their first psychiatric encounters. The most common false-positive diagnoses were bipolar disorder, depression, and anxiety disorders. Another large-scale outpatient study found that clinicians in routine practice diagnosed BPD in only 0.4% of almost 500 patients seen, compared to 14.4% prevalence derived when using structured interview with those very same patients. Importantly, when clinicians were provided with the findings from the structured interviews, the likelihood of the BPD diagnosis increased from 0.4 to 9.5%. Clearly the information from the structured interviews had clinical utility because the information from the structured interviews was used two-thirds of the time.

Clinicians who do not use structured or formal assessments of BPD are very likely to miss many cases of BPD, which can result in incomplete treatment. Therefore, it is recommended that clinicians formally assess for BPD as part of routine practice. It is particularly important to do so when a patient meets criteria for a disorder commonly comorbid with BPD (major depression, bipolar disorder, an anxiety disorder, posttraumatic stress disorder, or a substance use disorder). A comorbid BPD diagnosis will likely affect the course and outcome if not addressed. Likewise, complex comorbidity and/or a history of being diagnosed with various psychological disorders would also suggest to clinicians that they should formally assess for BPD. Although common comorbidities (e.g. major depression) may require simultaneous treatment with BPD, it is important not to assume that treatment of these conditions will result in the remission of BPD and privilege those treatments to the neglect of treating BPD. The evidence strongly suggests the contrary.

Treatment

BPD has historically been thought to be difficult to treat because patients frequently do not adhere to treatment recommendations, use services chaotically, and repeatedly drop out of treatment. Many clinicians are intimidated by the prospect of treating BPD patients and are often pessimistic about the outcome of treatment. Psychotherapists treating patients with BPD have displayed high levels of burnout and have been known to be prone to enactments and even engagement in iatrogenic behaviors. However, controlled trials strongly suggest that, contrary to popular belief, BPD is a treatable disorder.

Psychotherapy

There are now several treatments – deriving from both the cognitive-behavioral and psychodynamic traditions – that have shown efficacy in randomized controlled trials and are now available to clinicians and their patients. Although these treatments are often derived from either a cognitive-behavioral or psychodynamic tradition, they all tend to be either explicitly or implicitly integrative. In addition, there is a short-term psychoeducational, skills-based group called STEPPS, which has been found effective as an adjunct with other psychological treatments, and the American Psychiatric Association practice guidelines referred to General Psychiatric Management in conjunction with psychodynamic psychotherapy designed specifically for BPD has been shown to be efficacious. Thus, practitioners and patients have a range of options across a number of orientations available to them. Although DBT has been tested in more randomized controlled trials than the other treatments, findings from both direct comparisons and meta-analytic studies are clear that there is no advantage provided by DBT compared with these other approaches. Thus, there are a number of equally good treatments available to patients with BPD and there is no credible or reliable evidence that any one treatment is significantly better than any other.

Treatment Length

Because BPD is a chronic disorder that has developed over many years, it will most likely require a longer-term treatment that meets at least weekly. To date, all efficacious treatments

for BPD are a multiyear process (although most have only examined efficacy after one year of treatment). These treatments tend to be very intense and for two to five hours a week.

Expected Outcomes

Given the heterogeneity of BPD, having different treatment options is important because it is unlikely that any one treatment will be useful for all patients. Findings from randomized controlled trials (RCTs) suggest that about 50–60% of patients make symptomatic improvements within a year of treatment. Many of these individuals show changes within four to six months of treatment. Despite positive findings from RCTs, almost half the patients in treatment are not responding, regardless of treatment. Additionally, although many patients have shown symptomatic improvement and even diagnostic remission, they still experienced significant social and functional impairments. Thus, a significant portion of individuals receiving an efficacious treatment are not improving, and these individuals might be better served in different treatments.

Therapist Training

Although many of the existing empirically supported psychotherapies share many techniques with standard cognitive-behavioral therapy (CBT) and psychodynamic (PDT) treatments as they are commonly practiced in the community, it is important to note that there is little evidence that unmodified CBT or PDT (or humanistic) treatments are of benefit for those with BPD. The one RCT comparing standard CBT with treatment as usual found no reliable differences favoring CBT. The empirically supported treatments such as DBT, MBT, TFP among others have all been significantly modified from standard CBT and PDT approaches. Examples of modifications include provision of supervision or intervision, the explication of a coherent model of the problem and treatment, an increased attention to explicit frame issues, as well as a clear focus and priorities, vigilance for indications of colluding with the patient, acting out or iatrogenic behaviors on the therapist's part, and integration with other services among other aspects. These modifications are important and therefore it is recommended that clinicians who treat individuals with BPD have training in one or more of the empirically supported treatments and employ evidence-based principles deriving from these treatments and should not be using unmodified CBT and PDT.

Medications

Medications appear useful as adjunctive in the treatment of BPD but are generally not thought to be sufficient by themselves. No one specific medication has been shown to be efficacious in the treatment of BPD, which has led to a medication approach of targeting specific symptom domains rather than the disorder as a whole. The symptom domains of affect/mood, cognitive-perceptual processes, and impulsivity are frequent targets. However, this approach has become problematic, as the algorithms become quickly outdated, and the approach has led to increased rates of medication use and complicated polypharmacology issues. Such polypharmacotherapy has been associated with a number of untoward effects, including paradoxical side effects, adverse events, iatrogenic symptoms, and negative health

outcomes such as obesity and diabetes (being on three or more psychotropic medications is a greater risk factor for obesity than a family history of obesity or a sedentary lifestyle). Additionally, prescribed medications are often used in drug overdoses. There is some evidence for the superiority of monopharmacotherapy with BPD patients and for selecting medications based on tolerability and safety rather than symptom picture. Additionally, some RCTs have convincingly shown decreases in medication use related to psychotherapy efficacy.

Community Recommendations

BPD is a heterogeneous disorder. Only about 50% of patients respond to any of these treatments, and treatment responses, while clinically significant, are nonetheless incomplete. Hence, it is recommended that communities have several of the evidence-based treatments available to patients and that therapists consider obtaining expertise in more than one evidence-based therapy. Given the heterogeneity seen in BPD, it might be useful if the approaches available included both CBT- and PDT-based treatments.

Antisocial Personality Disorder

Olivia Choy

Nanyang Technological University

Antisocial personality disorder (ASPD) describes a pervasive pattern of disregard for, and violation of, the rights of others that begins in childhood or early adolescence and continues into adulthood. According to the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-V; American Psychiatric Association (APA), 2013), the diagnostic criteria includes repeated lawbreaking, deceitfulness, impulsivity, irritability and aggression, recklessness, consistent irresponsibility, and remorselessness. Diagnosis is also contingent on evidence of conduct disorder (CD) before age 15 years. Approximately 25–50% of individuals with CD meet ASPD criteria. Although greater severity of CD and childhood-onset rather than adolescent-onset CD have been associated with higher ASPD risk, it has been suggested that the type of adolescent antisocial behavior (rule-breaking, rather than aggression) constitutes the strongest predictor of ASPD symptoms.

In the general population, estimates of the lifetime prevalence rate are 1–4%. As ASPD is closely linked to violence and crime, it is overrepresented in the criminal justice system. Approximately 30% and 40–80% of individuals are diagnosed with ASPD in civil psychiatric facilities and forensic or correctional settings, respectively.

ASPD, particularly in males, has been consistently associated with higher recidivism rates. One study found that 41% of offenders with ASPD who were released from high-security settings reoffended within two years. Within a correctional setting, however, a study on prison systems in the United States revealed that an ASPD diagnosis could not predict offenders who would engage in institutional misconduct during their first year of incarceration. Empirical evidence suggests that the only aspect of the diagnosis that showed any potential utility for forecasting misconduct is CD symptom count.

Conceptualization and Categorization

Although the definition of ASPD was first modeled after psychopathy in its introduction in the DSM-III (APA, 1980), unlike psychopathy, ASPD diagnosis is primarily behaviorally based. It excludes several personality traits characteristic of psychopathy such as glibness, grandiosity, and callousness (see Hare, 1991). There remains a debate however, as to whether psychopathy is a more severe form of ASPD or if both constructs reflect separate diagnoses. Complications in treatment development may arise if the two disorders are deemed clinically interchangeable.

At the epidemiological and etiological levels, several findings support a distinction between psychopathy and ASPD. First, estimates of the prevalence of ASPD and psychopathy differ. An asymmetric association has been reliably found whereby most psychopathic individuals meet criteria for ASPD, but many with ASPD do not meet criteria for psychopathy. Second, differences between ASPD-diagnosed individuals with and without psychopathy have been observed. For example, male ASPD offenders with low psychopathy scores were documented to commit more perseverative errors and responses in the Wisconsin Card Sorting Test than those with high psychopathy scores. In another study, structural brain differences were noted. ASPD-diagnosed violent offenders with psychopathy displayed lower gray matter volumes in the superior/medial prefrontal cortex and temporal poles compared to individuals with ASPD but not psychopathy. Moreover, with respect to the amygdala, ASPD individuals without psychopathy exhibited hyperactivity in this brain region, while those with psychopathy showed hypoactivity in response to threat. These differences support the notion that psychopathy and ASPD may represent separate clinical constructs.

Other conceptual debates regarding ASPD involve the contention that there is too much commonality with other psychiatric disorders and the diagnosis is too broad. Another issue concerns the application of ASPD to racial and ethnic minority groups with histories of oppression. It has been argued that the diagnosis may be unfairly applied to impoverished groups for whom antisocial behaviors may be part of an adaptive survival strategy. This emphasizes the importance of taking into account cultural context in diagnosing and treating ASPD.

Sex Differences

ASPD is more common in men than women. Studies document that 2–6% of males and 0.5–2% of females in the general population meet diagnostic criteria. This pattern is replicated in criminal justice settings. Although there are some differences in prevalence rates across countries, a review of studies worldwide indicated that 47% of male prisoners were diagnosed with ASPD, while 21% of female prisoners received the diagnosis. Explanations for the sex difference are not well-investigated. In perhaps the only study on this topic, the sex difference in ASPD was found to be partly accounted for by lower gray matter volumes in three regions of the prefrontal cortex.

Unlike the prevalence ratio of men to women, a smaller body of research exists on sex differences regarding correlates of ASPD. Research has found that compared to men, women with ASPD reported more childhood emotional and sexual abuse, parent-related

adverse events in childhood, and adverse events during adulthood. Although ASPD has been consistently documented as a risk factor for intimate partner violence, there is a stronger association between male ASPD and reports of physical partner violence perpetration and victimization compared to female ASPD.

Comorbidities with other psychiatric disorders also differ between ASPD-diagnosed males and females. For instance, the percentage of ASPD individuals with comorbid borderline and histrionic personality disorders has been documented to be higher among women than men. Females with ASPD have also been suggested to be more vulnerable to substance use disorders. Conversely, more ASPD-diagnosed men have cocaine use disorder.

Association with Other Disorders

Besides psychopathy, evidence from epidemiological samples indicates that anxiety disorders, especially social anxiety disorder and posttraumatic stress disorder, are associated with ASPD. This finding is observed across countries and after adjusting for differences in sociodemographic characteristics and other psychiatric comorbidity. Individuals with ASPD also tend to have a higher prevalence of alcohol, drug, and nicotine dependence than those without ASPD. The high comorbidity is observed even if a substance use disorder has not been diagnosed or if the substance use is legal. Additionally, ASPD diagnoses are particularly prevalent among schizophrenia patients with a history of violence. One study found that the prevalence of schizophrenia was 6.9 and 11.8 times higher among ASPD-diagnosed men and women, respectively, compared to the general population. ASPD is also comorbid with attention deficit hyperactivity disorder, depression, borderline personality disorder, bipolar disorder, and sexual disorders. This has led to the suggestion that the treatment of individuals with ASPD should focus on the management of comorbid psychiatric disorders.

Etiology

Research on putative etiological mechanisms suggests that biological and psychosocial factors contribute to the development of ASPD. A genetic basis to ASPD is supported by the finding that a first-degree biological relative with ASPD constitutes a risk factor for the disorder. Specifically, the risk to biological relatives has been reported to be higher for females rather than males with ASPD. One of the few studies examining the heritability of the personality disorder in men found that 69% and 31% of the variance in ASPD was attributed to genetic and individual-specific environmental influences, respectively. Genetic influences have been found to be largely responsible for the initial level of ASPD symptoms, while non-shared environmental influences were more responsible for change. Longitudinal studies suggest that genetic effects on ASPD traits increase throughout adolescence but stabilize in early adulthood. Additional research is needed, however, to reveal consistent findings on specific candidate genetic variants for ASPD.

Neuroimaging studies have documented that ASPD likely has a neurobiological basis involving structural and functional brain abnormalities, with key impairments commonly found in the prefrontal and temporal cortices. One of the first structural brain imaging

studies of antisocial adults documented an 11% and 14.7% reduction in gray matter volume in the prefrontal cortex of men with ASPD compared to normal controls and a psychiatric control group respectively. Given evidence of gray matter reductions in similar regions among youths with conduct problems, it may be that the brain deficits associated with ASPD are sustained from childhood to adolescence to adulthood. These brain imaging findings are consistent with meta-analytic evidence that executive functioning is impaired in ASPD groups, with a small effect size. Impaired inhibitory control and decision-making have been implicated in ASPD, even in milder manifestations of the disorder.

In addition to abnormalities in the fronto-temporal network, reduced activity in the anterior cingulate, amygdala, and cerebellum have been documented in violent offenders with ASPD compared to nonoffenders. Several recent studies have found an increase in putamen volume in ASPD individuals compared to controls. A difference in the corpus callosum has also been reported between the two groups, with a larger volume exhibited among individuals with ASPD. Overall, reduced whole brain volume has also been observed in an ASPD group, which could be symptomatic of generalized atrophy or attributable to neurodevelopmental abnormalities resulting in reduced cerebrum size. Taken together, these studies provide evidence for the neural mechanisms underlying ASPD.

From a psychological perspective, intelligence has been found to be negatively associated with ASPD. There is also a small body of research documenting that deficits in mindfulness and impairments in mentalization, which encompasses the ability to reflect and think about one's mental states, are related to ASPD traits. Psychosocial risk factors for ASPD that have been consistently found across studies include more strained family relationships, child maltreatment, parental substance abuse, lower income, childhood residential mobility, and bullying.

Treatment

As the prevalence of ASPD is much higher in clinical populations, treatment options for ASPD are typically designed to treat comorbid psychiatric diagnoses or target a specific behavior. Interventions for ASPD have been psychological or pharmacological. Medications suggested as potentially beneficial for ASPD include mood stabilizers, antipsychotics, selective serotonin reuptake inhibitors, and anti-convulsants. One study on the treatment of ASPD with clozapine found that it reduced the clinical severity of the disorder. Promising psychological interventions include cognitive behavioral therapy and contingency management for men with ASPD and cocaine dependency. However, evidence for the efficacy of interventions is generally weak. At present, reviews of pharmacological and psychological interventions reveal that there is insufficient information to provide recommendations for any treatment for ASPD.

Current Emphases and Future Directions for Research

Although, historically, the examination of antisocial traits in females has received little attention, increased empirical attention is being paid to the prevalence, manifestation, and assessment of ASPD in female populations. In addition to studying female samples

across age ranges and settings, calls have been made for a more detailed examination of sex differences in individual ASPD criterion endorsement, as it has been suggested that sex differences in ASPD prevalence may be due to the emphasis on violent and aggressive behavior in the DSM criteria, which is biased against women.

Moreover, Section III of the *DSM* 5 (American Psychiatric Association (APA), 2013) includes an alternative model for personality disorders that emphasizes a dimensional ASPD model with a psychopathy specifier. Several studies have begun to examine aspects of the newly developed Section III trait model in relation to psychopathy. Future research on the psychopathy specifier will be needed to test whether its inclusion adds incremental utility to the understanding of ASPD.

Obsessive-Compulsive Personality Disorder

Nicole M. Cain and Thomas P. Mounsey

Long Island University

Obsessive-compulsive personality disorder (OCPD), as defined in the *Diagnostic and Statistical Manual of Mental Disorders* (DSM), is a mental disorder characterized by a chronic maladaptive pattern of excessive perfectionism, preoccupation with orderliness and detail, and need for control over one's environment that leads to significant distress or impairment across work, school, and social functioning. Individuals diagnosed with OCPD are reluctant to delegate tasks and work to others, find it difficult to relax, feel obligated to plan out their activities to the minute, and find unstructured time intolerable. In addition, they are often characterized as rigid and controlling in their relationships with others.

A Historical Overview of OCPD

There has been considerable interest in OCPD spanning over 100 years, with a rich historical context in psychoanalytic thinking. For example, Pierre Janet in 1904 first described the development of frank obsessions and compulsions as being preceded by a period he described as a "psychasthenic state," which was characterized by the sense that actions were performed incompletely and thus needed to be done perfectly, as well as a strong focus on order and uniformity. Following Janet's observations, Sigmund Freud in 1908 proposed the construct of the "anal character," which was typified by obstinacy, orderliness, and parsimony (or frugality). For many years, psychoanalysts used the term "obsessive-compulsive neurosis" to describe the features of OCPD.

OCPD was first included in the second edition of the DSM (DSM-II) and initial conceptualizations of the disorder were largely based on Janet's psychasthenic state and Freud's anal character. A subsequent revision of DSM OCPD criteria for the third edition (DSM-III) was highly influenced by the passive-ambivalent character described by Theodore Millon in 1981 as an individual who was serious minded, efficient, rule conscious, and lacking in emotional expression. This emphasis on Millon's research resulted in the inclusion of criteria related to indecisiveness and restricted expression of affect as part of the OCPD diagnosis. These

two criteria were retained in DSM-III-R, but were subsequently deleted in DSM-IV due to their inability to distinguish OCPD from other personality disorders.

The criteria for OCPD were not revised between DSM-IV, DSM-IV-TR, and DSM-V and currently an individual must meet four of the eight following criteria to receive the diagnosis: (1) is preoccupied with details, rules, lists, order organization, or schedules to the extent that the major point of the activity is lost; (2) shows a perfectionism that interferes with task completion (e.g. is unable to complete a project because his or her own overly strict standards are not met); (3) is excessively devoted to work and productivity to the exclusion of leisure activities and friendships (not accounted for by obvious economic necessity); (4) is overconscientious, scrupulous, and inflexible about matters of morality, ethics, or values (not accounted for by cultural or religious identification); (5) is unable to discard worn-out or worthless objects even when they have no sentimental value; (6) is reluctant to delegate tasks or to work with others unless they submit to exactly his or her way of doing things; (7) adopts a miserly spending style toward both self and others; money is viewed as something to be hoarded for future catastrophes; and (8) shows rigidity and stubbornness.

Empirical Evaluations of DSM OCPD

Although OCPD has been a clinically recognized syndrome for over 100 years, there is a relative lack of empirical research on this disorder. This is surprising considering that OCPD has been found to be the most prevalent personality disorder in the general population, with rates ranging from 7% to 8% in large epidemiological studies. In clinical populations, high prevalence rates are also reported and range from approximately 8% in outpatient settings to roughly 28% in inpatient settings. Research shows that there is a considerably higher prevalence of OCPD among men than women, with some studies reporting that men are twice as likely to receive an OCPD diagnosis as compared to women.

Empirical evaluations of DSM OCPD suggest problems with internal consistency, discriminant validity, and temporal stability. For example, investigations have reported internal consistencies for the OCPD criteria that range from insufficient to moderate. In addition, studies show that OCPD has a high degree of co-occurrence with paranoid personality disorder and schizoid personality disorder. Research on the temporal stability of OCPD has shown that roughly 60% of patients who are diagnosed with OCPD no longer meet DSM diagnostic threshold for the disorder after a 12-month follow-up period. This research also shows a remission rate of approximately 38% for OCPD during a 24-month follow-up period.

Several studies have investigated the internal factor structure of OCPD and have found mixed results. For example, some researchers have identified three main dimensions that underlie OCPD (rigidity, perfectionism, and miserliness), which resemble the stubbornness, orderliness, and parsimony initially described by Freud's "anal character." Other researchers have found support for only two dimensions underlying OCPD, though the exact two dimensions differ across studies. Some studies show that the two dimensions are perfectionism and rigidity, while other studies found support for perfectionism and aggressiveness as the two dimensions. Future research on the internal factor structure of DSM OCPD is needed.

Finally, research suggests that the criterion for perfectionism is the best overall predictor of the OCPD diagnosis while the criteria for miserliness and hoarding behavior

(e.g. unable to discard worn-out or worthless objects even when they have no sentimental value) are the worst predictors of the diagnosis. Interestingly, researchers also find that the preoccupation with details criterion is the best predictor of OCPD after a 24-month follow-up period.

Debates Surrounding the OCPD Diagnosis

One of the main debates associated with the OCPD diagnosis is how to best distinguish it from obsessive-compulsive disorder (OCD). The symptoms of OCD are characterized by recurrent, intrusive, and distressing thoughts, images, or impulses (obsessions) and repetitive mental or behavioral acts that the individual feels driven to perform (compulsions) to prevent or reduce distress. While distinct mental disorders in DSM, the overlap in symptom presentations between OCPD and OCD can lead to difficulty differentiating them in clinical practice. For example, while excessive list making can be viewed as a preoccupation with details characteristic of OCPD, it can also be viewed as a compulsion if it is repetitive, time-consuming, and distressing. Similarly, perfectionism is an OCPD criterion and also a symptom of OCD if it involves the need for order, symmetry, and arranging. In fact, prevalence data shows elevated rates of OCPD (approximately 45%) in individuals diagnosed with OCD, suggesting a high degree of diagnostic overlap between these two disorders. Patients with co-occurring OCPD and OCD report a significantly younger age of onset for their OCD symptoms, poorer psychosocial functioning, and a more chronic course of illness. Some researchers have suggested that the presence of co-occurring OCPD may in fact represent a possible subtype of OCD patients, while other researchers argue that OCPD is a distinct diagnosis within the OCD spectrum.

Despite similarities between some OCPD criteria and the obsessions and compulsions of OCD, there are distinct differences between these disorders, particularly in terms of the functional aspects of symptoms (i.e. what motivates the individual to display the symptom). In OCD, obsessions are intrusive, distressing, and generally recognized by the individual as dysfunctional. In contrast, individuals with OCPD often view their traits and symptomatic behaviors as appropriate and correct responses to environmental demands, despite their associated reports of functional impairment in work, school, and relationships.

Treatment Considerations for OCPD

Despite high clinical prevalence rates, there are currently no empirically validated treatments for OCPD. While there is no single treatment model for OCPD, there are several important factors to consider in treatment planning and assessment. The literature regarding treatment-seeking behavior in OCPD has been mixed. Some researchers have found that individuals with OCPD often seek treatment on their own because they are aware of their difficulties. However, other studies have shown that OCPD symptoms related to reluctance to delegate, perfectionism, and rigidity/stubbornness led to these individuals being less likely to seek treatment on their own. Researchers have also found that OCPD was a unique predictor of fewer treatment sessions attended in long-term psychodynamic psychotherapy.

One of the main problems with studying specific treatment modalities for OCPD is that most treatment studies do not separate personality disorders from other major mental disorders, such as depression, anxiety, and OCD. For example, one study examined the effectiveness of cognitive therapy (CT) and interpersonal therapy (IPT) in a sample of depressed patients with co-occurring OCPD or avoidant personality disorder. They found that IPT was significantly more effective in reducing depressed mood with increasing OCPD features as compared to avoidant personality disorder features. In a follow-up study examining the effectiveness of a brief time-limited psychodynamic psychotherapy for depressed and anxious patients with co-occurring OCPD or avoidant personality disorder, the researchers found that while both groups improved significantly on depression, the patients with co-occurring OCPD remained in treatment for significantly more sessions and were less likely to meet diagnostic thresholds for their OCPD symptoms as compared to patients with co-occurring avoidant personality disorder. Given the mixed findings in the treatment literature, more research is needed on treatment considerations for OCPD specifically.

One area for future study is the "positive side effects" of OCPD noted by researchers and clinicians that may prevent these individuals from seeking treatment. Data has suggested that OCPD may in fact enhance life and work success. For example, a few researchers have noted a negative relationship between OCPD and poor functioning in employment. Clinicians caution that these "positive effects" may lead the individual with OCPD to not seek treatment for symptoms that may otherwise be impairing and distressing. Several clinical theorists have hypothesized that individuals with OCPD may in fact function adequately for quite some time, but may eventually begin to feel distressed as they start to realize that they are not as successful in their work and social relationships as others. More longitudinal treatment studies on the course and outcome of OCPD are needed.

Narcissistic Personality Disorder

Kenneth N. Levy and Lia K. Rosenstein

Pennsylvania State University

Introduction

Although references to narcissism and later narcissistic personality have long appeared in the psychiatric and psychological literature, the concept of narcissistic personality disorder (NPD) was first introduced by Heinz Kohut and appeared in the DSM only in 1980. Beginning with its inception in DSM-III, NPD has been characterized by a pervasive pattern of grandiosity, feeling privileged, entitled, and expecting preferential treatment, as well as displaying an exaggerated sense of self-importance and showing arrogant and haughty behaviors or attitudes. Research on NPD has been relatively sparse compared to other personality disorders leading the disorder being considered controversial and its validity questioned. However, in recent years there has been a burgeoning research literature and with it increasing acceptance of its validity and clinical utility.

Clinical Presentation

NPD is a complex disorder that varies substantially in clinical presentation. Across all personality disorders, NPD spans the broadest spectrum of severity, from extremely high-functioning individuals that often present as charismatic and charming, to low-functioning individuals with a number of problematic comorbidities and functional impairment.

DSM-IV and DSM-V include nine criteria for NPD: a grandiose sense of self-importance, preoccupation with fantasies of grandeur, the belief that one is special and unique, requiring excessive admiration, having a sense of entitlement, being interpersonally exploitative, lacking empathy, having envy for others or believing others are envious of oneself, and showing arrogant and haughty behaviors and attitudes. These criteria emphasizing a sense of grandiosity, however, miss key dynamics seen in individuals with NPD, including vulnerable self-esteem, feelings of inferiority, emptiness, boredom, and affective reactivity and distress (Cain, Pincus, & Ansell, 2008).

Numerous theorists have suggested categorical subtypes of narcissism capturing the distinction between the more overt, grandiose presentation, as described in the DSM, and the more covert, vulnerable presentation. However, recent formulations note that both grandiose and vulnerable presentations can have overt and covert manifestations (Cain, Pincus, & Ansell, 2008). Although many contemporary theorists and researchers have emphasized categorical distinctions among narcissistic individuals, many other clinical writers have stressed that grandiose mental states oscillate or co-occur with vulnerable mental states. Kernberg (1975/1985) noted that the grandiose and vulnerable expressions may reflect different clinical manifestations of the disorder, with some traits being overt and others covert. He contended that narcissistic individuals hold contradictory views of the self that vacillate between the expression of grandiose and vulnerable aspects.

Epidemiology

Consistent with disorders such as schizophrenia, bipolar, and autism, epidemiological studies in community samples indicate a prevalence for NPD between less than 1% and 6.2%, with a mean prevalence of 1.06% (Quirk et al., 2016). It is likely that the prevalence estimates of NPD drawn from epidemiological studies are low in part due to the face validity of the criteria. Furthermore, those with NPD may purposely, out of social desirability, or unconsciously, out of defensiveness, hide or omit important information or interpret and present events in self-serving ways. The patient self-report is thus often unreliable.

As to be expected, prevalence rates of NPD are higher among clinical samples with estimates between 2.3% and 17% (Hörz-Sagstetter et al., 2017). A survey of almost 2,000 experienced psychiatrists and psychologists found that 76% reported treating a patient with NPD in the last six months (Westen, 1997). These findings suggest that NPD is commonly seen by clinicians.

Comorbidity with Other Psychological Disorders

NPD is frequently comorbid with other disorders, particularly substance use disorders, bipolar disorder, and other personality disorders (Zimmerman et al., 2005). NPD most commonly co-occurs with antisocial, histrionic, schizotypal, and borderline personality disorders (BPD) (Levy, Chauhan, Clarkin, Wasserman, & Reynoso, 2009). As with many personality disorders, comorbid disorders are often what first brings individuals with NDP to clinical attention, and the degree of comorbidity is linked to severity (Caligor, Levy, & Yeomans, 2015).

Grandiose and vulnerable narcissistic subtypes are associated with different patterns of comorbidity (Levy, 2012). Depression and anxiety are more common in the vulnerable narcissistic group, as are nonsuicidal self-injury and suicide attempts (Pincus & Lukowitsky, 2010). Grandiose traits tend to be related to substance abuse and comorbidity with antisocial and paranoid personality disorder (Russ, Shedler, & Bradley, 2008). Notably, comorbidity with antisocial personality disorder has the most profound negative impact on prognosis.

Assessment and Diagnosis

Without a systematic assessment of NPD criteria, the disorder often goes unrecognized and thus undiagnosed. However, even with a systematic assessment, the assessment and diagnosis of NPD can be difficult. First, the presentation can be subtle. This is especially true in higher-functioning NPD patients who can be charming or convincing in their perspective, thus obfuscating the dysfunctional dynamics. It is also important to assess for the more vulnerable and covert aspects of narcissism that are potentially less readily observable. Attention to and skill in addressing difficult subjects is needed on the part of the clinician and informant information is often crucial.

Common differential diagnoses for NPD include bipolar disorder, depressive disorders, anxiety disorders, and substance abuse. It is important to decipher whether presenting symptoms signal a comorbid disorder or are better attributed to underlying personality pathology. While manic states can mimic many of the features of grandiose narcissism, the admiration seeking and devaluation of others characteristic of NPD are typically absent in manic individuals. Similarly, chronic substance abuse can affect psychological functioning to simulate NPD. Assessing the chronicity and personality functioning beyond periods of excessive substance use may help disentangle this presentation. Symptoms associated with depressive and anxiety disorders overlap with features of vulnerable narcissism. One can avoid missing the NPD diagnosis by careful evaluation of the patient's sense of self and interpersonal functioning, with more covert grandiosity and a dearth of meaningful relationships signaling personality pathology. Furthermore, other personality disorders including BPD, histrionic, and antisocial personality disorder are common differentials. It is the characteristic grandiosity and need for admiration that most clearly distinguishes NPD from these disorders.

Treatment

The efficacy of psychotherapeutic and psychopharmacological treatment for NPD has not been systematically or empirically investigated. Clinical practice guidelines for the disorder have yet to be formulated, and recommendations for psychotherapeutic management of patients with NPD are primarily based on clinical experience and theoretical formulations.

The grandiosity and defensiveness that characterize NPD make engagement in any form of psychotherapy difficult. These patients are often unable to admit weaknesses, do not appreciate the effect their behavior has on others, and struggle to process and integrate feedback. A consistent finding in the literature is that in patients presenting with major psychiatric disorders, comorbid NPD increases the likelihood of treatment dropout and may slow symptom change. Hilsenroth and colleagues (1998) found that patients with NPD had the highest dropout rate (64%) in a study of early termination in a university-based community clinic. Consistent with this finding, narcissistic grandiosity (but not narcissistic vulnerability) predicted client-initiated termination of psychotherapy at a community mental health center (Ellison et al., 2013).

Psychotherapy

Psychodynamic formulations have led to the proliferation of different treatment approaches, and case reports suggest that these treatments can be effective for some patients. Most influential have been those of Kernberg (1970) and Kohut (1971), each of which focuses on clinical developments in the relationship between therapist and patient in long-term psychotherapy.

In the absence of empirically supported treatments for narcissistic pathology, extrapolating principles from efficacious treatments for near-neighbor disorders with treatment modifications based on theoretical and clinical rationales regarding differences in the disorders. Thus, for patients with NPD, we recommend using empirically supported treatments for BPD that have adaptations for NPD. In particular, we recommend transference-focused psychotherapy (TFP), schema-focused psychotherapy, or dialectical behavior therapy (DBT). All three treatments target psychological capacities thought to underlie and organize descriptive features of NPD.

Treatment Length

Because NPD is a chronic disorder that has developed over many years, it will most likely require a longer-term treatment that meets at least weekly. Treatments designed for near-neighbor disorders such as BPD tend to be long-term. Most are conceptualized as lasting between one and three years or longer; however, more research is needed in this area.

Expected Outcomes

Because of a lack of controlled treatment studies, the expected outcome of treatment is uncertain and probably variable. Based on clinical experience and expertise, Kernberg (1975/1985) suggests that narcissism tends to decrease with age and these individuals may be more amenable to treatment later in life, although he also notes that some individuals with narcissism worsen as they age as their lofty expectations remain unmet or as difficulties associated with the aging process are experienced as an intolerable insult. Consistent with the idea that narcissism lessens over time, a longitudinal study at McLean Hospital following formerly hospitalized patients with NPD found that after three years, only a small portion of patients continued to meet criteria for the disorder (Ronningstam, Gunderson, & Lyons, 1995). Extrapolating from these findings should remain tentative due to small samples, selection bias, and loss of data to follow-up. Additional studies are needed.

Therapist Training

Although, at this time, there are no RCTs of manualized treatments for NPD, a number of scholars have articulated clinical rationale for how best to approach those with NPD or significant NPD traits. It is recommended that therapists treating those with narcissistic pathology, at the very least, be well versed in a well-articulated and coherent approach toward the treatment of these patients. Training in one of the empirically supported treatments for BPD that have been adapted or for which principles have been modified for narcissistic pathology is recommended. One aspect of these treatments that should be emphasized is the importance of supervision or intervision for therapists treating individuals with NPD.

Medications

Pharmacological treatments of NPD have not been studied, and psychopharmacologic intervention is largely symptom driven rather than specific to the diagnosis. At this time, little is known about the overall efficacy of psychotropic medications for the treatment of NPD above and beyond psychotherapy.

Summary and Recommendations

NPD is a heterogeneous disorder that is as common as schizophrenia, bipolar disorder, and autism. It is highly comorbid with a range of disorders yet is frequently unrecognized, especially if not assessed. NPD and NPD traits put patients at risk for dropout and interfere with progress in psychotherapy. We therefore recommend that clinicians are vigilant for indications of NPD or NPD traits. Such vigilance is facilitated by assessing for narcissism during intake interviews, and the use of structured interviews is recommended. Because no randomized control trials have been performed, it is recommended that clinicians adapt an empirically supported treatment for a near-neighbor disorder such as BPD. Problems with narcissism have been discussed by clinical theorists for a number of evidence-based treatments for BPD, most extensively for TFP. In an RCT for BPD, TFP has been shown to reduce dropout among those high in narcissism as compared with DBT and a supportive psychotherapy. Although promising, these results must be replicated.

Schizotypal Personality Disorder

Keri Ka-Yee Wong[1] and Adrian Raine[2]

[1] *University of Cambridge*
[2] *University of Pennsylvania*

Schizotypal personality disorder (SPD) is characterized by cognitive, perceptual, social, interpersonal, and behavioral deficits that vary along a continuum of severity. Historically, the diagnostic criteria of SPD were based on two converging lines of research from observations of patients with borderline personality who exhibited attenuated schizophrenia-spectrum traits, and observations of relatives of patients with schizophrenia who exhibited peculiar thinking and social functioning.

A recent large-scale review has shown that just under 4% of individuals from the United States suffer from SPD (Pulay et al., 2009). Individuals were at greater risk for SPD if they were male (4.2%; vs. female 3.7%), separated/divorced/widowed, and received lower income compared to their counterparts.

According to DSM-V, meeting five of the nine features qualifies a diagnosis of SPD: *ideas of reference* (e.g. the feeling that the individual is the impetus of social events); *odd beliefs and magical thinking* (e.g. bizarre beliefs/fantasies that influence behavior yet contradict social norms); *unusual perceptual experiences* (e.g. seeing things that no one else can see); *suspiciousness/paranoia* (e.g. unfounded persecutory thoughts); *social anxiety* (e.g. excessive worries that do not decrease overtime); *lack of close friends* (e.g. no intimate relationships); *blunted/constricted affect* (e.g. flat/limited emotional response); *odd behavior* (e.g. peculiar dress style/behavior); and *disorganized thinking and speech* (e.g. vague/convoluted speech). Symptoms of SPD are sometimes referred to as positive (magical thinking, perceptual abnormalities, ideas of reference) and negative (few friends, social anxiety, blunted affect) features.

The last two decades have witnessed a strong increase in research on schizotypy both in clinical and community populations. A recent PsycInfo search across 27 databases returned 2,240 publications, 32% of which were published in the last five years. Such growth in research interest could be attributed to three reasons, all of which predicate on the dimensional nature of SPD.

First, schizotypal traits exist on a continuum of severity. On the one end of the spectrum are clinical patients who suffer severe, persistent SPD symptoms (1%–3%) and on the other end are individuals in the general population who exhibit attenuated, infrequent traits (0.7%–5%). Understanding that SPD traits exist at the community level has spurred new research questions and possibilities pertaining to the etiology of SPD. Numerous studies to date confirm that schizotypy exists in the community and can be screened for reliably. For instance, 55% of individuals scoring in the top 10% of the Schizotypal Personality Questionnaire (SPQ) receive a diagnosis of clinical schizotypy (Raine, 1991). Thus, community studies of SPD have the potential to unravel developmental precursors of SPD.

Second, in the last two decades, schizotypy research has become an international endeavor. In addition to the continual interest in the etiology of SPD and schizotypy, roughly 10 to 15 publications annually have focused on validating assessments of schizotypal traits across cultures and in younger populations, broadening the scope of research participants culturally and developmentally.

Third, supporting evidence for schizotypy as a construct offers researchers an avenue to understand the development and etiology of schizophrenia-spectrum disorders. For example, genetic studies have found that relatives of schizophrenia patients were more likely to exhibit symptoms of schizotypy compared to controls (Battaglia et al., 1995), suggesting that a better understanding of schizotypy may inform our understanding of schizophrenia. Prospective longitudinal studies that assessed the same cohort of individuals over time have also documented a 20%–40% conversion rate to schizophrenia among individuals who received a diagnosis of schizotypy early on in life (Larson et al., 2010). Although generally lower rates have been found in undergraduate community populations, these findings suggest that disabling disorders like schizophrenia may have its roots in the form of SPD in early development.

Multidimensionality

SPD and schizotypy have consistently been found to be a multidimensional construct. Though findings have been mixed, the most commonly reported finding in the literature is a three-factor structure: *cognitive-perceptual disturbances* (ideas of reference, odd beliefs, perceptual disturbances, and paranoia/suspiciousness), *interpersonal deficits* (lack of close friends, social anxiety, paranoia/suspiciousness), and *disorganized behavior* (odd speech/thought, blunted affect, odd behavior). Recent findings have indicated that the cognitive-perceptual and disorganized factors exhibit higher sensitivity and discriminate validity in the SPD diagnosis compared to other personality disorders in the DSM-IV. In particular, paranoia/suspiciousness, one of the most common symptoms in patients with schizophrenia, has been found to cross-load on two factors and exist at attenuated levels in community young adults and youths (Wong et al., 2014). There is growing research interest on whether other symptoms exist earlier on in development.

Assessment

Categorical (clinical) and dimensional (personality) approaches predominate the assessment of schizotypal personality. Informing the clinical literature are clinical diagnostic instruments that include the Structured Clinical Interview for DSM-IV Axis II Personality

Disorders, the Structured Interview for Schizotypy, and its revised version, which assesses a broad range of schizotypal symptoms within the context of the family and signs in first-degree relatives of schizophrenia patients and normal subjects. Complementing the categorical approach is the dimensional approach, which primarily consists of self-report questionnaires; namely, the pioneering Chapman et al.'s (1976) "psychosis-proneness" scales of physical and social anhedonia and Raine's SPQ (1991), which has been modeled on the DSM-III diagnostic criteria for schizotypal personality, with shortened (SPQ-B) and child-appropriate versions (SPQ-C) that extend the research scope to include younger children (Liu et al., 2019). The Oxford-Liverpool Inventory of Feelings and Experiences is another frequently used scale, as is the Rust Inventory of Schizotypal Cognitions, the Community Assessment of Psychic Experiences, and the Schizotypal Personality Scale.

What Are the Causes?

Psychosocial influences. Cross-sectional and prospective studies using both self-report and official records have observed that schizotypals are more likely to report child abuse, poor parental bonding/attachment, and trauma (including bullying and PTSD) compared with controls (Cutajar et al., 2010; Schürhoff, et al., 2009). Prospective attachment studies converge on the finding that poor parental bonding, that is anxious attachment (denoted by an anxious child in the absence of an attachment figure), is linked with positive schizotypy, and avoidant attachment (denoted by a child who shows little emotional distress in the absence of an attachment figure) has been linked with both positive and negative schizotypy (Korver-Nieberg et al., 2014). In the maltreatment literature, neglect appears to be central in schizotypals' lives. Specifically, victims of physical neglect have a 4.9-fold increase in SPD (Johnson et al., 2000). In a recent longitudinal study, children left home alone at age 3 were more likely to report higher levels of psychotic symptoms and antisocial behaviors and schizotypal traits and crime at ages 17 and 23 years, respectively, compared with children cared for by their parents/relatives (Wong, Raine, & Venables, 2018). This further supports a social explanation for schizotypy. Why psychosocial factors should result in schizotypal symptoms remains largely unknown, albeit some speculate that early abuse, neglect, and stress may result in structural and functional brain differences that give rise to schizotypal symptoms (Cannon et al., 1994) or in some cases, cause children to be more prone to becoming bully victims at a young age (Wong & Raine, 2019).

Genetic and neurodevelopment. Family studies have provided initial evidence that SPD is genetically associated with schizophrenia and that it is genetically related to itself. In particular, cognitive-perceptual features of SPD are genetically unrelated to schizophrenia, but are related to hostility, aggression, and affective instability (Dinn et al., 2002; Wong & Raine, 2019). Initial work at the symptom level, such as paranoia, also suggests that it is partially heritable (Zhou et al., 2018). This latter literature examining the symptom level along a dimension and the SPD-externalizing behaviors link, though growing, is still limited.

In terms of neurodevelopmental links to schizotypy, results from the Mauritius Child Health Project and an independently Finnish sample demonstrated that influenza exposure in the fifth month of pregnancy has been linked to positive symptoms of schizotypy at age 17, while negative symptoms at the same age have been linked with cold temperature exposure in the second trimester (Venables, 1996). Birth complications (i.e. low birth

weight and obstetric complications) and prenatal stress have also been associated with more cognitive-perceptual and disorganized features of schizotypy in early childhood and later adulthood, respectively (Machon et al., 2005), while prenatal malnutrition is linked to higher levels of schizotypy in adulthood.

Psychophysiology. The psychophysiological evidence for SPD is extensive and mirrors the psychophysiological deficits found in schizophrenia patients. Raine and colleagues (2002) found that increased orienting and arousal at age 3 predisposes to increased schizotypal personality 20 years later. Eye-tracking impairments and startle-blink reflex have consistently been observed in schizotypals. Furthermore, a reduction in the suppression of auditory P50 and P300 event-related-potential have been found in SPD patients and individuals with schizotypy, which indicates impaired selective attention (Niznikiewicz et al., 2009). One hypothesis is that these impairments may explain why patients with SPD fail to filter out irrelevant external stimuli that could contribute to their distorted cognitive-perceptual features.

Neurocognition and brain imaging. A review of the brain-imaging studies suggests that the most impaired areas found in both schizotypal personality and SPD individuals include: executive functions, sustained attention, working memory, verbal and spatial learning and memory, latent inhibition, negative priming, hemisphere asymmetry, and motor skills (Raine, 2006). These studies report increased prefrontal activation as measured by EEG, and the performance of schizotypals tends to fall between the range of normal controls and schizophrenia patients. However, a few studies have also documented enhanced creativity/ divergent thinking in schizotypy; which has been attributed to increased right hemisphere functioning and right prefrontal activation. Schizotypals underperform on facial emotional recognition tasks, struggle to label positive emotions, fail to think in another person's perspective (poor theory of mind), and overrespond to hostile/threatening stimuli compared to controls. A review of brain structure studies (n=17) found that SPD patients have abnormalities paralleling those found in schizophrenia patients in the superior temporal gyrus, parahippocampus, corpus callosum, thalamus, and septum pellucidum, as well as in total cerebrospinal fluid volume (Dickey et al., 2002). However, unlike schizophrenic patients, SPD patients showed normal functioning in the medial temporal lobes. On balance, the imaging findings suggest that SPD represents a milder form of disease along the schizophrenia continuum.

What Are the Cures?

Given the literature on brain deficiencies, carefully designed randomized placebo-controlled trials (RCTs) of biosocial interventions on schizotypal traits have been promising. One stratified RCT showed that early environmental enrichment consisting of physical exercise, cognitive stimulation, and nutritional enhancement at 3–5 years both improved brain functioning at 11 years and reduced schizotypy at ages 17 and 23 years (Venables & Raine, 2012). Omega-3 supplementation in those at risk of schizophrenia has been shown to reduce later breakdown for schizophrenia, suggesting that this nutritional supplementation could be helpful in reducing schizotypal traits. It has also been suggested that other promising areas of research requiring the development of new child-appropriate

assessment tools may complement existing lines of intervention research using genetic designs and involve examining parent-child interactions and the transmission of schizotypal traits in early childhood (Wong & Esposito, 2019; Wong & Raine, 2018)

Avoidant Personality Disorder

Daniel Winarick and Aaron Bortz

Queens College–CUNY

Diagnostic Classification

In the fifth edition of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-V) published by the American Psychiatric Association (APA) (2013), avoidant personality disorder (AVPD) is defined as a persistent pattern of social reticence or avoidance, feelings of inadequacy and social incompetence, fear of rejection, and hypersensitivity to negative evaluation, beginning by early adulthood and present in a variety of contexts. It is classified as a Cluster C personality disorder (PD) by the DSM-V (American Psychiatric Association, 2013), and as with other PDs, it must reflect long-term, inflexible patterns of behavior, feelings, and thoughts, and cannot stem from substance use or other medical conditions.

Individuals with AVPD frequently desire isolation, feel unworthy or incompetent, and remain highly alert for any negative assessments by other people. According to the DSM-V (American Psychiatric Association, 2013), to be diagnosed with AVPD, at least four of the following seven diagnostic criteria must be present: (1) due to fears of rejection and criticism, an avoidance of activities that require significant interaction with other people; (2) an unwillingness to get involved in a relationship unless acceptance or approval is assured; (3) restrained or inhibited behavior in serious emotional relationships, for the purpose of avoiding humiliation and ridicule; (4) an undivided focus on preparing for and avoiding criticism, embarrassment, or rejection in social situations; (5) reserved or inhibited behavior in new interpersonal situations because of overwhelming feelings of incompetence; (6) a view of the self as socially challenged and inferior to others; (7) an unwillingness to participate in novel activities or take personal risks because they may lead to shame or humiliation.

In addition to this categorical approach to diagnostic classification, the DSM-V (American Psychiatric Association, 2013) features a proposed dimensional model for PDs. The alternative model involves measuring degrees of impairment in personality functioning, namely self-definition (identity, self-direction) and interpersonal capabilities (empathy, intimacy). The model also evaluates PDs based on the severity of certain pathological traits; for AVPD, these are detachment and negative affect. According to the model, detachment in AVPD

may manifest as social withdrawal or reticence, avoidance of intimacy, or anhedonia, and the trait of negative affect is characterized by anxiousness. AVPD identity-related impairments include low self-esteem and excessive shame, while the impairment for self-direction involves a disinclination to take risks and participate in activities involving social interaction. The empathy impairment can manifest as a preoccupation with rejection influenced by distorted assumptions of what other people are thinking, and impaired intimacy can include diminished mutuality or reciprocity within a close relationship, stemming from fears of humiliation.

This alternative approach in the DSM-V draws on the paradigm of the Five Factor Model (FFM) of personality traits. Dimensional trait models such as the FFM conceptualize PDs in terms of maladaptive and more severe versions of normal personality traits, which include extraversion, agreeableness, and neuroticism. Though additional research is needed (Winarick, 2017), the FFM model has received support in existing research findings for its characterization of AVPD having a positive relationship with neuroticism and a negative relationship with extraversion.

There is also evidence of a possible relationship between changes in normal personality traits and changes in AVPD symptomatology over time. In one longitudinal study, a decrease in AVPD symptoms was associated with increases in dominance and affiliation, and a decrease in neuroticism (Wright et al., 2013); what drives these changes remains unclear, as does the nature of the interactions between the personality traits and AVPD symptomatology. Which symptoms tend to be the most resistant to change, and why? This research raises important questions about the trajectory of personality pathology, including AVPD, and the relationship between normal and maladaptive features of personality.

Prevalence and Comorbidity

Data from the 2001–2002 National Epidemiologic Survey on Alcohol and Related Conditions (NESARC) suggest a prevalence of approximately 2.4% for AVPD in the US population. A revised analysis of NESARC data, which did not accept PD criteria unless they also engendered a significant amount of impairment and distress, found an estimated prevalence of 1.2%, with the AVPD diagnosis more common among women (Trull et al., 2010).

AVPD is comorbid with a number of other disorders. Evidence from clinical samples includes a study involving 859 psychiatric outpatients where AVPD was the most common specific PD, with a prevalence rate of 14.7% (Zimmerman et al., 2005).

Depressive disorders and anxiety disorders are often diagnosed with AVPD, with especially high comorbidity between AVPD and social anxiety disorder or social phobia (McGlashan et al., 2000; Friborg et al., 2013). AVPD also frequently occurs with other PDs, including dependent disorder, borderline disorder, and the Cluster A group (schizotypal, schizoid, paranoid) (Winarick, 2017).

Research on genetic epidemiology has yielded evidence of a genetic liability shared between AVPD and schizoid personality disorder (SZPD) and between AVPD and schizophrenia spectrum pathology more generally, along with evidence of genetic risk factors common to AVPD and social anxiety disorder (Reichborn-Kjennerud, 2010).

Diagnostic Overlap with SZPD and Social Anxiety Disorder

A discussion of the historical development of AVPD as a construct can be found in Sanislaw et al. (2012). Descriptions of personality types exhibiting characteristics associated with AVPD emerged during the first half of the twentieth century. The first two editions of the DSM did not include a distinct AVPD diagnostic classification; the characteristics of avoidant personality were absorbed into the DSM's schizoid personality construct.

In the late 1960s, Theodore Millon drew on social learning theory to argue for a distinction between avoidant and schizoid personalities, with an avoidant personality characterized by a pattern of active detachment from interpersonal relationships, in contrast to the passive detachment of the schizoid personality. AVPD was later incorporated into the DSM-III (American Psychiatric Association, 1980) as its own diagnostic entity. Modifications were made to some of its criteria across subsequent editions, in part to address its overlap with social anxiety disorder and SZPD.

AVPD and SZPD share important features, chiefly social withdrawal and isolation, though different underlying reasons have been given for these behaviors; individuals with SZPD reportedly lack a desire to form relationships, while individuals with AVPD want to form relationships but avoid doing so out of a fear of rejection, embarrassment, and shame (Winarick, 2017).

Research involving a nonclinical population provides evidence that AVPD and SZPD may share common features: sensitivity to rejection, internalized shame, attachment avoidance, and an immature defense style (Winarick, 2013). However, evidence from the same work suggests that AVPD is associated with a greater degree of rejection sensitivity and shame, higher levels of attachment anxiety, and a stronger need to belong; furthermore, AVPD may also be associated with a mature or adaptive defense style, and not only with a maladaptive defense style (Winarick, 2013). In contrast, SZPD has a strong unique association with social anhedonia, and it may also be linked to lower empathy.

This evidence lends support to the DSM-V's current categorical model, which keeps AVPD and SZPD distinct (Winarick & Bornstein, 2015). It also raises questions about the DSM-V's alternative model, in which SZPD is no longer a distinct diagnostic classification, and where anhedonia is one of the possible criteria for detachment in AVPD. More research is needed to explore the commonalities between the two disorders and clarify their differences, including the quality of needing to belong that is associated with AVPD.

Social anxiety disorder also shares key features with AVPD. A body of literature supports the argument that there is not a qualitative difference between them and that they may be part of a continuum (Reich, 2009; Tillfors & Ekselius, 2009), with AVPD as a more severe form with stronger symptoms and more pervasive impairments. However, some question this idea and highlight possible meaningful features that are more characteristic of AVPD alone and might suggest qualitative differences (Hummelen et al., 2007; Lampe, 2015). The conceptualization of AVPD and social anxiety disorder, the relationship between them, and the nature of their common features, risk factors, and potential differences continue to be investigated.

Etiology

Estimates of heritability for AVPD vary across studies, with one study calculating an estimate of 0.64 (Gjerde et al., 2012). Genetic factors may also contribute strongly to the stability of AVPD traits across different points in adulthood (Gjerde et al., 2015).

Possible childhood risk factors for AVPD include parental neglect (Johnson et al., 1999; Joyce et al., 2003), temperamental traits of anxiousness and shyness, and anxiety disorders during childhood and adolescence (Joyce et al., 2003). Explorations of childhood antecedents of AVPD include retrospective reports of relatively poor social ability in parents and other caretakers, fewer positive relationships with non-caretaking adults, and some signs of poorer social standing among peers and less involvement in activities (Rettew et al., 2003). The complex interplay of different factors, such as temperamental traits and children's interactions with parents (who have transmitted genetic information, modeled behaviors, and shaped other elements of childhood experience), warrants further study.

The second edition of the *Psychodynamic Diagnostic Manual* discusses "anxious avoidant personality organization" in childhood (Lingiardi & McWilliams, 2017, pp. 346–347), linking it to certain qualities of temperament, such as fearfulness and shyness, and an influence from caregivers with similar temperamental traits who may have difficulty managing their own anxiety and may negatively affect their child's development across different dimensions. These dimensions include the extent to which children develop an internalized sense of themselves as inadequate, the severity of their fear of embarrassment and consequent social withdrawal, the extent to which they perceive other people as threatening, and the degree to which closeness to other people can be tolerated. Throughout childhood, individuals experiencing more severe anxiety and exhibiting more marked social inhibition may experience rejection that exacerbates maladaptive behavior, thoughts, and emotions. Similar reinforcing patterns can come into play during adulthood as well.

Treatment

The major negative effects of AVPD are most apparent in social and occupational functioning. The features of AVPD that may lead to severe social isolation, a limited or nonexistent support network, and struggles with employment and educational prospects could also serve as obstacles to effective therapy.

Individuals with AVPD will thoroughly scrutinize the actions and expressions of those they come in contact with, including therapists and other clinicians. Even the thought of criticism or negative attention produces feelings of anxiety and fear, and avoidance is a protective measure. Along with experiencing a fear of rejection, individuals with AVPD may not wish to take risks that potentially expose them to failure, including engaging with the demands of therapy (Newman, 1999).

Low self-esteem and fear of rejection make interpersonal contact extremely difficult for individuals with AVPD, even if they desire affection and possibly fantasize about relationships with others. They may act in a closed-off manner and not reveal much about themselves. Some research also links their struggles with interpersonal interactions to possible difficulties in thinking about and expressing their emotional and mental states (Procacci et al., 2007; Johansen et al., 2013).

A review of the literature on psychotherapeutic treatments for AVPD (Weinbrecht et al., 2016) highlights a paucity of research on this topic; one key reason may be the close relationship between AVPD and social anxiety disorder, which has received more attention. The best types of treatment or therapeutic approaches for individuals with AVPD need to be better established.

Sadism and Masochism

Natasha Knack[1], Lisa Murphy[2], and J. Paul Fedoroff[2]

[1] *The Royal's Institute of Mental Health Research*
[2] *The Royal*

The terms *sadism* and *masochism* were coined by German psychiatrist Richard von Krafft-Ebing in his book *Psychopathia Sexualis*, first published in 1886. He described sadism as deriving sexual pleasure from inflicting pain on another person and named the term after the Marquis de Sade, who wrote the novel *120 Days of Sodom* in 1785 (first published in 1904 under the name *Les 120 Journées de Sodome ou l'école du Libertinage*), which included graphic descriptions of sexually motivated violence. Conversely, he described masochism as obtaining sexual pleasure from receiving pain and cruelty inflicted by another person and named this term after Leopold von Sacher-Masoch, who authored *Venus in Furs* (1870), a novel about a man who persuades a woman to use him as her slave and degrade him sexually and otherwise. Although they were originally understood as being two distinct concepts, British psychologist Havelock Ellis promoted the idea that sadism and masochism are actually closely related concepts as they describe complementary forms of behavior. This new interpretation formed the basis of the modern conception of sadomasochism (SM).

Since SM was first introduced, individuals have been attempting to accurately define this phenomenon. As it is common for people to pathologize things that they do not understand or have difficulty explaining, it is not surprising that psychology, psychiatry, and other disciplines have traditionally described SM as a symptom of psychopathology or a sexual perversion resulting from some form of mental illness or trauma, such as childhood sexual abuse. More modern research has refuted many of these theories, forcing people to re-evaluate their understanding of SM and subsequently prompting the search for a new definition.

Numerous definitions have been proposed throughout the last century; however, a commonly accepted definition of SM behavior does not currently exist. This may be due to the fact that SM comprises a wide range of sexual behaviors and is interpreted subjectively; meaning different things, to different people, at different times, and being credited with varying degrees of importance. The elements that are most consistent among definitions

include a prearranged unequal distribution of power and the giving and receiving of physical pain and/or psychological humiliation and subjugation, all of which is completely consensual and understood by all participants to be for the purpose of sexual pleasure. SM is often understood within the larger context of BDSM, an acronym used to describe a collection of interests and activities involving themes of bondage and discipline (B&D), dominance and submission (D/s), and sadism and masochism (SM), as it more accurately depicts the wide range of interests and behaviors associated with this practice.

Although SM itself is difficult to accurately define, there are a number of terms commonly associated with this practice that have more concrete definitions. A "scene" is a period of time during which two or more SM practitioners engage in a variety of predetermined behaviors for the purpose of obtaining sexual pleasure; participating in a scene is often referred to as *playing*. Scenes often include elements of role-play and may or may not involve explicit sexual activity such as genital stimulation, penetration, and/or orgasm.

The term *dominant* refers to a person who takes control within a relationship, while a *submissive* is someone who voluntarily relinquishes control to a dominant. It is important to note that not all dominants are sadists and not all submissives are masochists. These terms are more commonly used within the context of an ongoing relationship, whereas the terms "top" and "bottom" are used specifically to describe the role that each person assumes during a particular scene. Before a scene takes place, participants negotiate and establish the bottom's soft and hard limits; soft-limits are those that can be slightly pushed during the scene, as opposed to hard limits, which are boundaries that are not to be crossed. The use of a safe word, which is a preestablished term or phrase used by the bottom to indicate their current physical/emotional state, is intended to ensure that the bottom's limits are respected. One common example of this is the traffic light approach, where red means that the top should stop immediately, yellow signifies that a limit is being approached, and green is an indication to continue. The term *subspace* refers to the natural high that a bottom may experience during a scene, which is theoretically brought on by the release of endorphins in response to pain. *Aftercare* is an essential part of any SM scene that takes place when the scene has ended and involves the top comforting the bottom, showing appreciation for their strength and courage during the scene, treating any wounds that may have resulted, and providing them with food or water if necessary. Research has found that the aftercare period is often associated with increased levels of intimacy and bonding between partners.

Misunderstandings about SM and its practitioners continue to be prominent, despite the fact that the activities involved with this practice are not nearly as modern as is commonly assumed. The Kama Sutra, which is one of the earliest descriptions of human sexuality, not only compares sexual intercourse to a quarrel but also discusses a range of embraces including scratching, biting, and striking, and gives advice about where and how to administer these embraces, as well as the different sounds that will result. Other historical records have indicated that bondage, pain, and an unequal distribution of power have been a part of human sexual practices for thousands of years. More modern research has confirmed that the prevalence of SM is actually quite high, with some figures suggesting that BDSM practices are almost as common as non-BDSM sexual relations among same-sex adults. The male and female Kinsey surveys (conducted in 1948 and 1953, respectively) found that 50% of men and 54% of women reported responding at least somewhat erotically to being

bitten, and 24% of men and 12% of women experienced at least a mild erotic response to SM stories. A study by Richters et al. (2008) recruited a sample of over 19,000 Australian men and women, age 16 to 65, and found that, of the participants who were sexually active, 2.3% of men and 1.3% of women had engaged in BDSM within the year prior to the study. As of 2006, there were more than 500 groups dedicated to the practice of consensual SM in the United States alone, with members engaging in SM activities on a weekly, monthly, and/or annual basis.

The emergence of the internet has had a significant impact on the prevalence of SM behaviors, as it has provided a way for people to learn more about this topic and meet others who are interested in engaging in similar activities. For example, Fetlife.com is a social networking site for people interested in BDSM and other fetishes, which allows members to meet others with similar interests, find events in their area, as well as ask and answer questions related to their sexual interests. Between 2010 and 2013, over 1.3 million new members joined Fetlife.com, an increase of 231%.

Despite the fact that SM behaviors have existed for thousands of years and appear to be increasing in prevalence, people who engage in consensual SM are often stigmatized in a variety of life-altering ways, such as losing their jobs, failing to obtain security clearances, being denied custody of their children, or being victims of harassment and/or violence. In response to this social stigma, the National Coalition for Sexual Freedom (NCSF) was formed in 1997, with the goal of protecting the rights of those who engage in consensual BDSM by attempting to change how the general public, as well as the legal system, interprets these activities. Since that time, approximately 500 people per year have requested help from the NCSF when dealing with prejudice or prosecution related to their involvement with BDSM. The stigmatization faced by these individuals may be related to early theories that described SM as pathological, and promoted the idea that those who engaged in these behaviors must be antisocial, trying to escape their real lives, and/or using SM as an excuse for assaulting their partners.

Contrary to these early theories, current research indicates that not only are SM practitioners no more likely to suffer from psychopathology or escapist tendencies, they also tend to be emotionally, psychologically, and socially well-adjusted, possess a positive self-image, and often have higher levels of education and income compared to the general public. Research has also found that no significant differences exist between SM practitioners and the general public with regard to rates of unhappiness, anxiety, and sexual coercion (Richters et al., 2008). New theories about SM suggest that it is actually a healthy phenomenon, a form of sexual play that allows consensual adults to break-free of social norms and create novel, exciting, and intensely intimate experiences.

Individuals or couples who are interested in SM may choose to become part of a BDSM community. There are many possible reasons for choosing to become part of this community, including access to events such as SM conferences, workshops, parties, and community meetings. These events allow SM practitioners to meet and socialize with others who have similar interests, find potential partners, and discover and learn about different SM activities and techniques. BDSM communities also strive to ensure the safety of their members by providing safe play spaces, regularly discussing and implementing standards for safe practice, as well as identifying individuals who are not adhering to these standards and removing them from the community. It is important to note that BDSM communities are

not exclusively about sex. They also help members to normalize their sexual interests and behaviors, which may be stigmatized in other contexts, and provide members with a sense of kinship and a culture in which they can establish, cultivate, and/or come to terms with their identity as an SM practitioner.

To people outside of the BDSM community, it is not always clear that SM must be *consensual*, making it distinctly different from physical or sexual abuse, which by definition involves lack of consent. This misunderstanding may be due to the fact that consensual and criminal SM can, in some ways, resemble each other. For example, an unequal distribution of power, verbal degradation, and the infliction of physical pain may occur in both consensual SM and physical/sexual abuse. However, this resemblance exists *only* on the surface as there are several fundamental differences between these two types of behaviors. In addition to a lack of consent, abusive behaviors are often unpredictable, carried out with no consideration for the other person, and are often accompanied by guarantees that the behavior will not occur again. In contrast, consensual SM is a desired exchange of power that involves a great deal of communication and negotiation, promotes safety, and is used to bring about sexual pleasure and gratification for everyone involved. Additionally, in consensual SM it is actually the bottom (submissive) who retains control of the situation, as they decide what will take place during the scene, determine the limits that can be pushed and those that must be respected, and may even give specific instructions to the top (dominant) during the negotiation process.

Another important factor is that partners who engage in consensual SM draw a clear line between behaviors that are acceptable during everyday life and those that are only acceptable during a scene. Since SM is a subjective experience, where this line is drawn may be significantly different depending on the type of relationship. There are a number of different types of SM partnerships, including relationships that are casual and exist only within a particular scene, partners who play together regularly but do not have a relationship outside of this context, partners who play together regularly and also have an ongoing relationship unrelated to this practice, and relationships where partners play together regularly but also maintain their dominant and submissive roles in their day-to-day lives (often referred to as 24/7 relationships). Owing to the intensity of their shared experiences, SM partners often have increased levels of intimacy, trust, and communication, regardless of the type of relationship.

Research has found that SM practitioners are typically well-adjusted and comfortable with their sexual preferences; however, there are individuals who experience distress because of their interest in SM and who may seek help for this issue. In order to ensure that these individuals are not pathologized or stigmatized for their sexual interests, it is essential that clinicians working with this population have a thorough understanding of consensual SM and how it differs from physical/sexual abuse. Clinicians working with this population must also be cognizant of their own values, beliefs, and perceptions about SM if they are to avoid letting these personal judgments influence the treatment of their patients. It is imperative that clinicians also keep in mind that simply having an interest in SM does not mean that an individual meets the diagnostic criteria for sexual sadism or sexual masochism, as the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-V) explicitly states that these should only be considered mental disorders when they cause the individual to experience significant distress or interpersonal difficulty. It has been found

that even when SM practitioners do seek help, the focus of therapy is rarely their interest in SM, but rather issues that are indirectly related to this interest, including relationship problems, shame, guilt, and pre-existing mental health issues (e.g. depression, anxiety, etc.). SM may be considered a deviant sexual interest, but the fact remains that deviant only means a departure from what is considered normal – it is not synonymous with dysfunction.

Emotion Regulation and Psychopathology

Erika S. DeJonghe

California State Polytechnic University, Pomona

Definitions of Emotion and Emotion Regulation

Writers in the area of emotion regulation typically use the term *emotion* to indicate specific, marked affective states, such as sadness or anger, whereas *affect* is used as a general or umbrella term for all psychological states that a person finds to be pleasant or unpleasant (DeSteno, Gross, & Kubzansky, 2013; Gross, 2015). Gross (2015) suggests that the general construct of affect includes emotions, stress responses (psychological and physiological responses to stressful events), and moods (lower intensity, more pervasive, psychological reactions that persist over a greater period of time than emotions). Broadly speaking, the term *emotion regulation* refers to a variety of strategies that people may employ to manage their own feelings or the feelings of others. Gross (2015) defines emotion regulation as "the activation of a goal to influence the emotion trajectory," i.e. actively increasing or decreasing emotions. Emotion regulation may be internal (changing one's own emotions) or external (changing the emotions of someone else, such as when a parent helps a child calm down) (Gross, 2015).

Emotion regulation may take many forms. DeSteno and colleagues (2013) describe emotion regulation strategies that include "situation selection" (placing oneself in situations that will elicit more pleasant emotions), "situation modification" (making changes to one's surroundings to improve mood), "attentional deployment" (shifting one's attentional focus towards less distressing or more positive-emotion inducing stimuli), "cognitive change" (modifying one's thoughts to improve mood), and "response modulation" (directly altering physical or behavioral aspects of an emotional response). According to this model, a person facing an unpleasant work environment might change jobs or transfer to another department (situation selection), redecorate the office to make being at work pleasant (situation modification), intentionally ignore problematic co-workers (attentional deployment), reframe a boss's criticism as feedback that will help a career trajectory in the long-term (cognitive change), or practice relaxation and

deep-breathing techniques to facilitate relaxation when becoming annoyed by co-workers (response modulation). While most of these examples involve a person using emotion regulation strategies to increase positive emotions and decrease negative emotions, emotion regulation may also be used to increase negative emotions (e.g., helping an assault victim become angry with his/her attacker rather than engaging in self-blame) or to decrease positive emotions (e.g., suppressing a case of the "giggles" when situationally inappropriate) (Gross, 2015).

Development of Emotion Regulation

Emotion regulation is typically understood as a fairly stable trait, which emerges in childhood. The bulk of the development of emotion regulation appears to occur in the first few years of life. Individual patterns of emotion regulation emerge and stabilize by age two, with minimal changes in the years that follow (Eisenberg, Spinrad, & Eggum, 2010). Early antecedents of the ability to regulate emotion have been measured even in infancy, expressed as temperamental tendencies to express emotion and recover from distress. Rothbart (1981) was among the earliest researchers to quantify temperament in the first year of life. She defined infant temperament as individual differences on two dimensions – reactivity and self-regulation. Later research has demonstrated that temperamental tendencies toward reactivity may be seen in early infancy and that self-control, including emotion regulation, develops as infants become capable of increasingly complex behaviors (Fox & Calkins, 2003). Fox and Calkins (2003) assert that, by the beginning of toddlerhood, the ability to direct attention and motor control are sufficiently developed to permit a child to employ basic emotion regulation strategies. In addition, considerable research suggests that early temperamental tendencies to display negative emotional reactions, in particular, are associated with self-control strategies later in infancy (for a review, see Fox & Calkins, 2003).

While temperamental tendencies to self-regulate are typically understood to be innate, considerable evidence also exists that the development of emotion regulation may be impacted by external factors, with parenting being the most salient external factor. Research on maternal emotion expression and emotion relation in young children reveals that when mothers express more positive vs. negative emotion, their young children are more likely to exhibit self-soothing (Bariola, Gullone, & Hughes, 2011). Based on a review of the extant literature, Morris, Silk, Steinberg, Myers, and Robinson (2007) posit that families influence children's developing emotion regulation via three mechanisms: modeling of emotion regulation practices by family members, direct parenting regarding emotion, and the general emotional climate of the family. The authors also point to mounting evidence that family influence on emotion regulation abilities may be an important mediator or the relationship between family context and psychosocial outcomes (Morris et al., 2007). However, the authors are careful to point out that the vast majority of this research has emphasized the mother–child relationship and that other familial relationships are under studied.

Emotion Regulation and Mental Health Problems

Deficits in emotion regulation have been found in a wide variety of psychological disorders in both children and adults (for reviews see Jazaieri, Urry, & Gross, 2013; Berking & Wupperman, 2012). Deficits in emotion regulation abilities have typically been linked to externalizing problems in children (Eisenberg et al., 2010), presumably because the deficits result in difficult inhibiting inappropriate external expressions of negative affect. For example, emotion regulation problems have been found to be associated with ADHD diagnosis, and it has been suggested that children who have emotion regulation problems may be at increased risk for ADHD as well as commonly co-morbid conditions such as oppositional defiant disorder, conduct disorder, anxiety, and depression (Steinberg & Drabick, 2015). Problems with emotion regulation have also been found to be associated with adolescent substance abuse (Poon, Turpyn, Hansen, Jacangelo, & Chaplin, 2015).

In adults, reliance on problematic emotion regulation strategies has been found to be more common in those diagnosed with specifically with eating disorders, including anorexia nervosa, bulimia nervosa, and binge-eating disorder (Brockmeyer, Skunde, Wu, Bresslein, Rudofsky, Herzog, & Friederich, 2013; Oldershaw, Lavender, Sallis, Stahl, & Schmidt, 2015). Problems with emotion regulation have also been found to be related to the development of PTSD following exposure to a potential traumatic event (Lilly & London, 2015). For example, in a sample of trauma-exposed refugees, Nickerson, Bryant, Schnyder, Schick, Mueller, and Morina (2015) found that emotion dysregulation mediated the relationship between environmental risk and psychological symptoms. Similarly, for victims of physical, sexual, or emotional abuse perpetrated by someone close to the victim, emotion regulation difficulties were found to mediate the relationships between trauma exposure and trauma, depression, and anxiety symptom expression (Goldsmith, Chesney, Heath, & Barlow, 2013).

Emotion regulation difficulties have also been found to be related to particular aspects of psychological disorders. For example, Tsypes, Aldao, and Mennin (2013) found that emotion regulation problems mediated the relationship between symptoms of generalized anxiety disorder and sleep disturbances. Specific behaviors associated with mental health problems, particularly self-harm, disordered eating, and substance abuse, have been found to be associated with deficits in emotion regulation (Buckholdt, Parra, Anestis, Lavender, Jobe-Shields, Tull, & Gratz, 2015). Examining the relationships between specific emotion regulation strategies and mental health diagnoses, D'Avanzato, Joormann, Seimer, and Gotlib (2013) found that participants with diagnoses of social anxiety disorder or major depressive disorder tended to be more likely to employ rumination or suppression of emotional expression and less likely to employ cognitive reappraisal as emotion regulation strategies.

Recently, psychotherapies have begun to address deficits in emotion regulation as a mechanism to improve mental health. Most notably, dialectical behavior therapy (Neacsiu, Bohus, & Linehan, 2014) was developed to address the deficits in emotion regulation that are understood to be central to borderline personality disorder and associated self-harm. A central component of DBT and other psychotherapies targeting improved ability to regulate emotion is the practice of "mindfulness," which helps the client learn to recognize and tolerate emotions as a precursor to learning to manage emotional responses (for a review, see Greenberg & Pascual-Leone, 2006).

Eating Disorders

Jennifer Barney, Arielle Wolinsky, and Adrienne S. Juarascio

Drexel University

Eating disorders (EDs) are complex psychiatric disorders characterized by disturbances in an individual's eating and related behaviors, resulting in psychological distress, health concerns, and reduced quality of life. These disorders can arise from many combinations of psychological, biological, and social risk factors and can lead to potentially life-threatening behaviors and thought patterns surrounding one's eating and weight. Individual variability of symptomology, diagnostic crossover, and difficulty distinguishing disordered eating from normal-range eating behaviors, often make diagnosing and treating EDs very difficult. While the Diagnostic and *Statistical Manual of Mental Disorders,* fifth edition (DSM-V), outlines some of the more common presentations of ED symptoms, (which are described in greater detail below), individual risk factors and various treatment methods that have been utilized for varying EDs are also reviewed.

Anorexia Nervosa

AN is characterized within the DSM-V as: (1) persistent restriction of energy intake resulting in significantly low body weight; (2) intense fear of gaining weight or becoming heavy, or persistent behaviors that interfere with necessary weight gain; and (3) disturbance in the way one's body weight or shape is experienced. Two subtypes may also be specified within the diagnosis of AN when appropriate: (1) Restricting, describing presentations of symptoms in which only caloric restriction and/or excessive exercise are present or (2) binge/purge (AN-BP), describing presentations where binge eating and purging behaviors (e.g. self-induced vomiting, laxative misuse) are also present, concurrent with the first three diagnostic AN criteria. Any patient presenting with binge/purge symptoms who is also underweight will be given a diagnosis of AN instead of bulimia nervosa, described below.

Bulimia Nervosa

Bulimia nervosa (BN) is characterized in the DSM-V as: (1) recurrent episodes of binge eating, (2) recurrent, inappropriate compensatory behavior in order to prevent weight gain such as: self-induced vomiting; misuse of laxatives, diuretics, or other medications; restricting caloric intake; or excessive exercise, (3) self-evaluation being unduly influenced by body shape and weight. Episodes of binge eating under the BN diagnosis are characterized as "Eating, in a discrete period of time (e.g. 2 hours), an amount of food that is definitely larger than most people would eat during a similar period of time under similar circumstances and having a sense of lack of control over the eating during the episode." For a diagnosis of BN to be made, these behaviors must be occurring, on average, at least once a week for at least three months.

Binge-Eating Disorder

Binge-eating disorder (BED) was added as its own categorical ED in DSM-V. Similar to BN, the first defining feature of BED is recurrent episodes of binge eating during which an individual consumes, in a discrete time period (e.g. 2 hours), an amount that is "definitely larger" than what most people typically consume in a similar span of time under similar circumstances. However, unlike bulimia nervosa, BED episodes of binge eating are not regularly followed by the use of inappropriate compensatory behaviors.

For a diagnosis of BED to be made, binge eating episodes must (a) occur on average at least once a week for three months, (b) occur in the absence of recurrent compensatory behaviors, (c) be associated with marked distress and a sense of "loss of control" while eating, and (d) have at least three of the following features: eating much more rapidly than normal; eating until uncomfortably full; eating in the absence of physical hunger; eating alone due to embarrassment about quantity of food one is consuming; and/or feeling disgusted with oneself, excessive guilt, or depressed after binging.

Other Feeding and Eating Disorders

Other feeding and eating disorders (OSFED) is an umbrella term for several other combinations of symptoms characteristic of EDs that cause clinically significant distress or impairment but do not meet the diagnostic criteria for AN, BN, or BED. Some presentations falling under this "catch-all" term have been clinically specified and include, but are not limited to, night eating syndrome (characterized by a delayed circadian pattern of food intake), atypical AN (all criteria for AN are met except that the individual is within or above normal range), purging disorder (recurrent purging (e.g. self-induced vomiting, laxative, or diuretic misuse) to control weight or shape in the absence of binge eating), and subthreshold BN or BED.

Risk Factors in Individual ED Development

Genetics

Genetics research to date has found moderate-to-high heritability of AN, BN, and BED and disordered eating symptoms in both males and females during adolescence and young adulthood. Other studies have similarly concluded that eating disorders have an increased prevalence in families that have biological relatives with eating disorders in comparison to the normative population. Non-overlapping environmental effects, such as exposure to the thin ideal and psychiatric morbidity, can explain the remaining variability in the development of an eating disorder. These environmental factors (e.g. family characteristics, peer influences, and socio-cultural traits) are explained in more detail below.

Personality Traits

Certain personality characteristics such as neuroticism and negative emotionality have been shown to predispose an individual to the development and maintenance of an eating disorder by impacting a person's typical pattern of thinking, emotions, and behavior across situations and various environmental situations. Perfectionism, described as having high standards of oneself and an overly critical self-evaluation, appears to be directly related to the onset of anorectic, but not bulimic, symptoms. However, the interaction between perfectionism and other intrapersonal factors such as low self-esteem, body dissatisfaction, and a drive for thinness, can increase an individual's risk for developing all eating disorder symptoms. Impulsivity prospectively predicts the development of binge eating and purging symptoms found in BN, BED, and AN-binge/purge type EDs. Negative urgency, a fact of impulsivity trait describing the tendency to engage in rash decision making and action when in distress appears to be the most predictive facet of impulsivity for the development of binge eating and purging symptoms.

Neurocognitive Processes

Certain deficits in neurocognitive processes have been seen at higher rates in ED populations. Cognitive flexibility, an individual's ability to shift between mental sets, multiple tasks, and operations, is impaired in individuals with AN and BN, but not in individuals with BED. Impaired inhibitory control, the ability to suppress an automatic response in favor of a less automatic one, is commonly found in individuals who engage in binge eating and/or purging.

Interpersonal Relations

Family members and peers can be strong social influences on the development of EDs. Living in an critical, hostile, and emotionally dismissive family environment is a potent risk factor for the development of an ED. Furthermore, family members (often mothers) may serve as role models for eating and body-image criticism for their children. Fathers

who tend to be authoritative and controlling can contribute to both the onset and the maintenance of eating disorder symptoms in their child. Research to date also suggests that sibling relationships may be the strongest models of weight concerns and muscular shape misperceptions within the immediate family environment.

Peer influence on the development of ED is not as clearly defined as is the familial influence on ED development. This is primarily due to the broadness and pervasiveness that peer influence has on individuals. The peer group is usually the main source of eating-related attitudes (e.g. thin ideal) and behaviors (e.g. dieting), often leading toward disordered eating patterns. In particular, those individuals who already suffer from disordered eating behaviors or thoughts and attitudes related to ED pathology appear to experience a worsening of ED symptoms if they are reinforced by their peers. Similarly, surrounding oneself with peers who have similar body-related beliefs and attitudes may lead an individual to adopt these same attitudes.

Socio-Cultural Influences

EDs were traditionally believed to primarily affect Caucasian adolescent and young adult women from high-income, industrialized Europe and North America. In these societies, food can be found in an abundance and there is a strongly held thin ideal. With the recent industrialization, modernization, and globalization of an increasing number of Asian and Arab countries, the prevalence of EDs has dramatically increased in these non-Western cultures. For example, the introduction of Westernized television in Fijian families' households had detrimental consequences for their adolescent daughters' eating attitudes and behaviors due to exposure to Western beauty norms.

Among the North American minority cultures, African American and Hispanic American populations are showing increased rates of BN and BED, and not AN, which can be explained by the larger body ideal present in these societies. Increased body-image concerns and higher rates of EDs in men are also being observed due to a societal shift in beauty and body ideals for males.

A Multi-Faceted Approach

The development of EDs is multifactorial and complex, including both intra- and interpersonal factors. In general, the strongest risk factors for both BN and AN are gender, weight and shape concerns, and a group of variables focusing on negative affect, neuroticism, and general psychiatric morbidity. Body dissatisfaction and weight and shape concerns are the strongest risk factors for the development of an eating disorder. No single factor can be identified as the primary causal influence on the development of an ED.

Treatments

Treatments for EDs require the clinician(s) involved to address a variety of specific, complex needs based on the presentation and severity of the diagnosed disorder. At present, the most effective approaches have included some form of psychotherapy combined with

increased attention to the patient's medical and nutritional needs in order to help the individual begin working toward more adaptive eating behaviors.

The treatment of AN typically involves three overarching components: (1) restoring body weight, (2) treating the psychological components related to the eating disorder, and (3) reducing and/or eliminating behaviors or thoughts that lead to maladaptive eating and weight loss. Currently, adults with AN show poor responses to psychological treatments, with most specialized treatments still showing relatively high relapse rates, patient drop-out, and/or minimal effect sizes within the RCTs that have been conducted. The current standard approaches to outpatient treatments for this disorder include psychodynamic and interpersonal therapies and manual-based approaches such as enhanced cognitive behavioral therapy, although no treatment appears to be significantly more effective than other treatment models. Family-based therapy, which utilizes the parents as a primary resource in the treatment process for adolescents struggling with AN, is an effective treatment for adolescents with AN, particularly within the first three years of the disorder's onset.

The current gold-standard approach to treating BN in an outpatient setting is cognitive behavioral therapy (CBT)/enhanced cognitive behavioral therapy (CBT-E), developed by Christopher Fairburn in 1981 and enhanced in 2008. CBT and CBT-E are designed to help patients regulate their maladaptive eating behaviors while identifying and working to change the key mechanisms maintaining the individual's disordered eating cycles. This model has been somewhat successful for BN patients; however, a large percentage experience only partial success with CBT or CBT-E alone. Other psychotherapy models that are currently used in comparison models or in conjunction with CBT for binge eating and BN patients are acceptance and commitment therapy, dialectical behavioral therapy, and interpersonal therapies. However, no other treatments have surpassed the efficacy of CBT/CBT-E. Researchers have also begun to implement CBT treatments and interpersonal Psychotherapy treatments for BED due to the empirical efficacy of these models for treating BN. Thus far, both models have found relatively similar results in the management of both short-term and long-term BED symptoms.

To highlight, a large component of what kind of treatment an ED patient receives is contingent upon the severity and persistence of the individual's ED symptoms. As previously stated, EDs are dangerous psychiatric disorders that can lead to significant medical complications and have particularly high mortality rates for individuals who suffer from them. Despite continued attempts at an outpatient level of care or who present with severe medical complications (e.g. dangerously low weight, significant malnutrition, electrolyte imbalances) those who have been struggling consistently may need to be hospitalized to address these concerns in addition to treating their other ED symptoms. In addition, various, more intense levels of care (e.g. residential treatment, day treatment, and intensive outpatient treatment), can be utilized for patients whose symptoms are not responding to standard weekly treatment approaches.

The wide variation of symptoms included amongst ED presentations typically requires the involvement of multiple treatment providers to effectively manage all aspects of the individual's well-being. These providers may include, but are not limited to: an individual therapist, a medical doctor (for management of physical symptoms); a nutritionist or registered dietician (to assist with eating regulation); and/or a psychiatrist (for medication management). Certain medications, primarily antidepressants (e.g. Prozac), have been prescribed, particularly

to patients struggling with BN, to help reduce symptoms thought to be correlated with the ED (e.g. anxiety, depression). Psychopharmacological success varies substantially and, due to high comorbidity rates of other psychiatric disorders among ED patients, it is difficult to differentiate symptoms and accurately prescribe appropriate medications.

Current Research

While there are current, "gold-standard" methods for treating EDs, the overall outcomes for many of these treatment models remain low, especially when compared to the treatment of other psychiatric disorders. Research is needed to improve the field's understanding of maintenance factors of EDs that may be efficacious to target within treatment models and to develop a better understanding of the biological and neurological contributors to the development and maintenance of EDs. Recent advancements in neuroimaging procedures are allowing psychologists to look at potential differences in neurological structures and functions occurring in individuals with EDs and various ED symptomologies, which could potentially assist in the development of increased efficacious treatments that address these deficits.

Neuropsychiatric Disorders

Robert S. Blumenfeld

California State Polytechnic University

Neuropsychiatric disorders are specific, clinically recognized conditions in which an individual's thoughts, perceptions, emotions and/or overt behavior cause suffering and interfere with the individual's daily functioning. What differentiates a "neuropsychiatric disorder" from the more common term "mental disorder" is not the disorder itself but rather the clinical emphasis. The *Diagnostic and Statistical Manual for Mental Disorders* fifth edition (DSM-V) recognizes over 450 mental disorders. These diagnoses are syndrome-based, that is, based on sets of behavioral symptoms, not with reference to mechanism or underlying brain pathology. For many mental disorders, the neural substrate is not (yet) known nor considered relevant for treatment. These disorders are not (yet) in the purview of neuropsychiatry and neuropsychiatric research. In contrast, neuropsychiatric disorders can be considered the subset of mental disorders for which there is some knowledge about the underlying brain pathology and most importantly, this pathology is relevant to treatment. Some of the most common and most studied neuropsychiatric disorders include schizophrenia, major depressive disorder and bipolar disorder. These disorders, by definition, have profound effects on an individual's expression of personality – negatively affecting comfort and willingness to engage in social interactions, attitudes about the self, mood, and disposition (Karsten et al., 2012; Kendler & Neale, 1993). For example, flat affect and lack of interest in social interactions are common so-called "negative" symptoms in schizophrenia. These patients also experience "positive" symptoms such as delusions, hallucinations, and racing thoughts. In chronic patients, both the negative and positive symptoms might be considered related to personality, because their presence can lead to a pervasive change in an individual's behavior and self-perceptions. Neuropsychiatric disorders have tremendous individual differences both in their behavioral expression and in their neural underpinnings. For example, in schizophrenia there is considerable heterogeneity in the presence of positive symptoms. Similarly, a major depression diagnosis captures a spectrum of behavior where individuals can vary greatly in their expression of depressive thoughts, actions and reported suffering. Historically, individual differences have been seen as reflecting variability around

categorical distinctions (e.g. the distinction between the subtypes of schizophrenia, or the distinction between schizophrenia and bipolar disorder). However, recent evidence from longitudinal epidemiological studies has challenged this basic assumption in support of the view that individual differences in symptoms reflect variability along a single unitary factor, the so-called "p-factor" or "psychopathology factor" that can explain variability in symptoms across diagnostic categories.

Individual Differences in Neuropsychiatry: Diagnostic and Practical Issues

Understanding the nature of inter-individual differences in symptom expression is a fundamental challenge in neuropsychiatry. In other fields of medicine, diagnoses need not be made purely based on symptoms as such diagnoses tend not to be reliable or stable. Unfortunately, however, in neuropsychiatry, clinicians often have little else to rely on. In essence, the symptoms and severities that are reported by individuals *are the disorder* and thus individual differences in symptom expression strongly determine diagnosis and treatment. As a result, a tremendous amount of research and debate in neuropsychiatry is focused on how individual differences in symptom expression are to be understood. Categorical models of mental disorders use the presence or absence of symptoms to cluster individuals into diagnostic categories and subcategories. For instance, in schizophrenia, clinicians using a categorical model might assign a patient to a diagnosis of schizophrenia of the disorganized type based on the presence or absence of incomprehensible speech or "word salad." In contrast, dimensional models use symptom severity, and not simply the presence or absence of symptoms, to scale a patients' disorder along several different dimensions. The same patient that might have been diagnosed with schizophrenia of the disorganized type according to a categorical framework, will now not get assigned to the disorganized subtype of schizophrenia but instead show high on disorganized symptoms. Dimensional models, in theory, should lead to more reliable and stable diagnoses and are certainly more appropriate for disorders such as personality disorders, for which patients present with behaviors that are just more extreme or severe versions of typical behaviors. These factors, in part, were the motivation for the movement from the DSM-IV's categorical models to DSM-V, which emphasizes the dimensional aspects of many mental and neuropsychiatric disorders.

   Nevertheless, even with the use of dimensional or even hybrid models, there are still fundamental challenges to understanding how symptoms relate to the underlying disorder, or indeed to understanding what the fundamental nature of neuropsychiatric disorders are. For instance, it has long been observed that symptom severity is associated with serial and nonserial comorbidity. That is, when an individual has severe symptoms they tend to get diagnosed with multiple diagnoses or move from one diagnosis to another sequentially. When researchers examined the factor structure in a very large set of longitudinal data tracking diagnoses across mental disorders, what they found was that a single factor could explain vulnerability of patients to a core set of symptoms (Caspi et al., 2014). This factor, called the p-factor (for psychopathology factor), indicates potentially that there is a single axis, rather than different dimensions or categories, that drives individual differences in

symptoms. The presence of a single underlying psychopathology factor might also have important implications for understanding the neural substrate underlying neuropsychiatric disorders as well.

The Neural Substrate of Neuropsychiatric Disorders

In the past 20 years, with the advent of neuroimaging methodologies such as positron emission tomography (PET) and magnetic resonance imaging (MRI) being used in clinical and translational research, we have learned much about the alterations in brain structure, brain function, and brain chemistry in patients with schizophrenia, major depression and bipolar disorder. Perhaps surprisingly, one broad conclusion is that the brain alterations seen in neuropsychiatric disorder are relatively subtle, especially compared to the neuropathology seen in neurodegenerative diseases such as Alzheimer's dementia, Huntington's disease, and Parkinson's disease. In the latter cases, brain pathology such as hippocampal and medial temporal lobe atrophy (Alzheimer's dementia), basal ganglia atrophy (Huntington's disease) and atrophy to the midbrain and substantia nigra (Parkinson's disease) can clearly be detected using structural MRI by a neurologist or radiologist and often can be used as a means of making a probable diagnosis. In most neuropsychiatric conditions however, patients' structural MRI scan will often look unremarkable from a radiological perspective. Studies using *functional* MRI (fMRI), a method that tracks brain activity via changes in blood oxygen, tend to be more sensitive. However, activity differences between patients and controls tend to be small and inter-individual differences in activity sometimes but not always correlate with symptoms or discriminate between diagnoses (Stephan et al., 2016). Thus, these studies seem to indicate that relatively subtle alterations in the structure and/or activity of individual brain regions underlie the symptoms of neuropsychiatric disorders.

Recently however, an alternative hypothesis has emerged that suggests neuropsychiatric disorders come about not through functional or structural alterations in individual brain regions but by higher-order alterations in the functional interactions amongst brain regions. These interactions, referred to as functional connectivity, can be measured *in vivo* using MRI, and using analyses based on a branch of applied math known as graph-theory, researchers have been able to examine the large-scale network properties of the healthy and patient brain in great detail. Such studies often find widespread alterations in the organization of brain functional connectivity with neuropsychiatric disorders. For instance, in schizophrenia, where the bulk of this research has been done, a growing number of studies find marked and specific alterations in functional connectivity. Studies find reduced functional connectivity at the overall whole network level (weaker connections), reductions in the clustering of connections between regions (propensity for regions to form sub-networks with shared connections), decreases in the "centrality" (how well connected a region is to every other region) of key hub regions in the brain, and in general more randomness in the wiring of functional connectivity (Crossley et al., 2014; Fornito, Zalesky, & Breakspear, 2015). Importantly, these network alterations have been shown to be related to behavioral symptoms (Fornito et al., 2015) in schizophrenia and other disorders. Most intriguing, from an individual difference perspective, is the emergence of the notion of the "connectional fingerprint." A connectional fingerprint, much as one's fingerprint or genetic

code uniquely specifies one's identity, could potentially specify one's unique profile of functional and structural brain connectivity (Edwin Thanarajah et al., 2016; Meyer-Lindenberg, 2009). However, a connectional fingerprint would actually carry information beyond identity – it would provide quantitative information about the functional and structural organization of an individual's brain. With research linking connectional fingerprints to symptoms, there is great potential for them to help individualize treatment and disentangle the complex alterations of brain–behavior relationships that underlie neuropsychiatric disorders.

Issues Associated with Personality in Neuropsychiatric Disorders

The set of mental disorders most associated with aberrant aspects of personality are the personality disorders. The DSM-V (as well as previous editions) classify these disorders as the set of mental disorders where an individual's thoughts, self-perceptions, perceptions of others, and actions toward others deviate significantly from the individual's culture and adversely affect an individual's daily functioning. Often these individuals rate at the extremes on Big 5 measures (Karsten et al., 2012). The DSM-V distinguishes 10 different types of personality disorders, once again, based on symptoms. Very little is known about underlying neuropathology in personality disorders. In the case of borderline personality disorder, there is some evidence of hippocampal atrophy (or just smaller hippocampal volumes) linked to experiences of childhood trauma. Interestingly, this is not unlike what is seen in patients with post-traumatic stress disorder (PTSD) (Brambilla et al., 2004). Clearly, there is need for more research in identifying stable neuropathology in personality disorders. Currently, although patients with personality disorders often receive medications to treat symptoms (typically because of major depression or other comorbidity), these disorders are not typically considered neuropsychiatric.

Issues of personality, however, are not restricted to just those diagnosed with a personality disorder. Indeed, clinical studies provide evidence that although personality measures remain valid and reliable in neuropsychiatric groups, common measures, such as the NEO-V, tend to fluctuate along with the disorder and along with treatment. For example, in major depressive disorder, patients tend to score higher in neuroticism and lower in extroversion, conscientiousness, and openness during a depressive episode (Costa, Bagby, Herbst, & McCrae, 2005) and some of these changes, particularly in regard to neuroticism, may persist after the depressive episode (Kendler & Neale, 1993). In other disorders such as schizophrenia, personality measures are also affected. For instance, patients with schizophrenia tend to show higher levels of neuroticism and lower levels of openness, agreeableness, extraversion, and conscientiousness compared to healthy control subjects (Camisa et al., 2005). Interestingly, recent large epidemiological studies tend to show a high-level of comorbidity of personality disorders in neuropsychiatric populations. One study estimates the prevalence of personality disorder with neuropsychiatric populations to be as high as one-third of patients (Zimmerman, Rothschild, & Chelminski, 2005).

Posttraumatic Stress Disorder

Erika S. DeJonghe[1] and Hope Alvizar[2]

[1] *California State Polytechnic University, Pomona*
[2] *David and Margaret Youth and Family Services*

Posttraumatic stress disorder (PTSD) is a syndrome that may emerge following a potentially traumatic event (PTE) in which a person witnesses actual or possible death, serious injury, or sexual violence. The *Diagnostic and Statistical Manual of Mental Disorders*, 5th edition (DSM-5, 2013) groups PTSD symptoms into four categories: intrusion symptoms (e.g. flashbacks or traumatic nightmares), avoidance symptoms (e.g. avoiding people or places related to the traumatic event), cognitive and mood symptoms (e.g. not being able to remember some or all of the traumatic event, self-blame, or blunting of positive emotions), and arousal and reactivity symptoms (e.g. increased startle response or difficulty concentrating).

Symptoms and Diagnosis

To meet DSM-5 criteria for a diagnosis of PTSD, a person must have directly experienced a PTE, witnessed the PTE happening to someone else, learned that a PTE happened to someone close to the person, or have had repeated or extreme exposure to unpleasant details of the traumatic events. Media exposure to PTEs are specifically excluded, unless the exposure occurs as art of the person's work. Thus, someone repeatedly viewing violence images in the course of their work, such as might be the case for a person investigating violent crimes, would be eligible for diagnosis. Prior to DSM-5, it was required that the traumatic event result in feelings of fear, helplessness, or horror, but this stipulation was removed. In addition to exposure to a PTE, diagnosis requires that a person exhibit symptoms which must include at least one intrusion symptom, one avoidance symptom, two cognitive or mood symptoms, and two arousal and reactivity symptoms. These symptoms must persist for at least one month, must cause significant distress or impairment, and cannot be due to the effects of medication or substance use (American Psychiatric Association, 2013).

A major change to the diagnosis of PTSD in DSM-5 has been the introduction of distinct diagnostic criteria for children under 7 years old. Exposure to a PTE for a child may include direct involvement, witnessing the PTE (excluding media exposure), or learning that a PTE happened to a parent or caregiver. Symptoms for children are slightly different from those listed for adults and are grouped into only three categories: intrusion symptoms (e.g. play reenactment of the PTE, nightmares which may or may not be explicitly linked to the PTE), avoidance/mood/cognitive symptoms (e.g. constriction of play, social withdrawal), and arousal and reactivity symptoms (e.g. irritability, aggression, or temper tantrums). As with adults, children must exhibit symptoms for at least one month, experience distress or impairment, and cannot be due to medical or substance use (American Psychiatric Association, 2013).

PTSD and the HPA Axis

In addition to the behavioral symptoms described above, exposure to trauma and the subsequent development of PTSD have been shown to be associated with changes to the functioning of the hypothalamic-pituitary-adrenal (HPA) axis. While, the specific nature of these changes is still not fully understood (de Kloet, Vermetten, Geuze, Kavelaars, Heijnen, & Westenberg, 2006), researchers concur that there appear to be changes in HPA-axis functioning that are apparent both in day-to-day living as well in response to a direct stressor such as a trauma reminder (de Kloet et al., 2006).

Prevalence Rates and Group Differences in Prevalence

Lifetime prevalence of PTSD in the United States is estimated at 8.7% and annual prevalence is estimated at 3.5%, with lower prevalence rates reported for Europe, and many Asian, African, and Latin American countries (American Psychiatric Association, 2013). Within the United States, research suggests that prevalence rates of PTSD vary across racial and ethnic groups as do the nature of the traumas that results in PTSD across groups. For example, data from a national survey found that lifetime prevalence rates of PTSD were higher for African Americans and lower for Asians (Roberts, Gilman, Breslau, Breslau, & Koenen, 2011). The same study (Roberts et al., 2011) found that Whites were generally more likely to experience any type of trauma, but that risk for exposure to child maltreatment was higher among African Americans and Hispanic Americans and risk for war-related trauma was higher among Asians, African American men, and Hispanic women. PTSD is often associated with other mental health problems. For example, a survey of women found that the majority (87.5%) of people who met criteria for PTSD had at least one additional diagnosis and that PTSD was significantly correlated with many other disorders (Perkonigg, Kessler, Storz, & Wittchen, 2000).

Perhaps the most commonly described group difference in prevalence rates of PTSD is the differences in trauma exposure and rates of diagnosis for men and women. Over the past decade, studies have indicated that men are more likely than women to be exposed to almost every type traumatic event (Blain, Galovski, & Robinson, 2010; Irish et al., 2011; Solomon, Gelkopf, & Bleich, 2005), with the exception of sexual and interpersonal violence (Blain, Galovski, & Robinson, 2010). Despite having lower rates of trauma exposure, women have

demonstrated a greater risk for developing PTSD following a traumatic event (Blain et al., 2010; Gil, Weinberg, Or-Chen, & Harel, 2015; Irish, Fischer, Fallon, Spoonster, Sledjeski, et al., 2011) and greater risk for PTSD to advance into a chronic condition (Blain et al., 2010).

Studies have indicated that the disparity between genders in the development of PTSD may be attributed to a difference in the perception of trauma and self-efficacy (Blain et al., 2010; Solomon et al., 2005). Women have been found to be more likely than men to perceive comparable traumatic events as more threatening and evaluate their ability to manage the traumatic event as ineffective (Irish et al., 2011; Solomon et al., 2005), which is consistent with findings that negative perceptions are associated with an increased risk for PTSD (Irish et al., 2011). Variations in coping mechanisms have also been attributed to gender differences in the development of PTSD. Women typically use an internalized approach to coping (Blain et al., 2010; Solomon et al., 2005), which involves focusing on their thoughts and emotions associated with the traumatic event (Solomon et al., 2005). Conversely, men typically use an externalized approach to coping, which involves focusing on the problem by recognizing and directly addressing stressors (Solomon et al., 2005).

Studies have also revealed gender differences in symptom profiles. Women often report more internalizing symptoms such as anxiety and depression, whereas men often report more externalizing symptoms such a substance abuse, irritability, impulsivity, and aggressive behavior (Blain et al., 2010; Solomon et al., 2005). Additionally, women commonly report more posttraumatic symptoms (Blain et al., 2010; Irish et al., 2011; Solomon et al., 2005) and higher levels of distress (Irish et al., 2011). Gender differences in symptom profiles have been attributed to social gender-role expectations. For example, the possibility of social stigma may be deterring males from reporting or seeking treatment for socially feminized symptoms such as depression (Solomon et al., 2005).

Risk and Protective Factors for the Development of PTSD

One important aspect of how individuals respond to PTEs appears to be an individual's cognitive response to a PTE. For example, Feldner, Lewis, Leen-Feldner, Schnurr, & Zvolensky (2006) found that anxiety sensitivity, a propensity to respond with further anxiety to symptoms associated with anxiety, moderated the relationship between traumatic events and PTSD symptoms. Similarly, an examination of personal resilience characteristics revealed that control, commitment, goal-orientation, self-esteem, adaptability, social skills, and humor were associated with greater physical and mental health, as well as lower PTSD symptom severity among survivors of violent trauma (Connor, Davidson, & Lee, 2003). In fact, research seems to suggest that the importance of dispositions toward certain cognitive responses as a potential risk factor in the wake of a PTE may extend beyond PTSD to other potential psychological sequelae. For example, Calvete, Estévez, & Corral (2007) found that cognitive schemas mediated the link between partner violence and depression.

Protective factors for the development of PTSD appear to include the presence of social support and active coping strategies. Generally, social support has been found to have both direct effects on mental health (Coker et al., 2002). Glass, Perrin, Campbell, & Soeken (2007) found that tangible social support moderated the relationship between being a victim of partner violence and PTSD symptoms. In addition, active coping with PTEs seems to be related to more positive outcomes. Reviere, Farber, Twomey, Okun, Jackson, Zanville,

& Kaslow (2007) found that, among a sample of low-income, African American women, qualitative research documented that women who attempted suicide were more likely to display less adaptive coping strategies focused on accommodating abusers, as compared to women who did not attempt suicide, whose coping strategies focused on leaving the relationships or avoiding harm.

Treatment

Fortunately, several psychotherapy treatments have received empirical support (for a review, see Bisson & Andrew, 2007). Treatments include exposure therapy (Foa, Rothbaum, Riggs, & Murdock, 1991) and stress inoculation treatment (Foa et al., 1991). Empirical support also exists for the use of eye movement desensitization and reprocessing (Bisson & Andrew, 2005). In addition to these psychotherapies, evidence suggests that selective serotonin reuptake inhibitors may be useful in treatment of PTSD (Albucher & Liberzon, 2002).

Individual Differences and Sleep Disorders

Kelly Donohue and Y. Evie Garcia

Northern Arizona University

Sleep is a physiological process necessary for refreshing and reinvigorating both mind and body. Sleep disorders may be diagnosed if sleep is consistently scant, excessive, fragmented, or fails to be restorative. Sleep disorders are commonly associated with physiological issues (e.g. pain, pulmonary disease, acid reflux) and neurological issues (e.g. brain injury or disease). Underlying sleep disorders may result in reports of feeling fatigued, irritable, or depressed. Poor concentration, memory problems, and general problems with cognitive or physical performance are also common complaints (Greenwalk & Sabini, 2009). Individual differences in sleep schedules depend on age, lifestyle, and individual needs for sleep based on biological, environmental, and behavioral factors (D'Cruz, & Vaughn, 2009). Sleep phase, amount of actual sleep (rather than time in bed), and biological-environmental interactions are important in diagnosing and treating sleep disorders.

Types of Sleep Disorders and Causes

Sleep Phase

The term *sleep phase* describes the time period when one is typically asleep. Sleep phase is determined by chronobiologic factors (biological cycles or rhythms) and is influenced by environment and behavior. Physiological urges that determine the onset of the sleep phase can be one source of disordered sleep. Common factors contributing to sleep phase disorders are jet lag (80% of business travelers report sleep disturbances), shift work, and blindness (due to inability to use light to set circadian rhythms; Fernandez, Eisenschenk, & Okun, 2009). *Delayed sleep phase syndrome* and *advanced sleep phase syndrome* are both sleep disorders that impact the time of day when fatigue and the urge to sleep are experienced. Advanced sleep onset syndrome is characterized by a natural urge for sleep in the early evening, followed by awakening very early in the morning. Conversely, the hallmark of delayed sleep phase syndrome is an inclination to delay sleep onset to the early morning

hours and sleep until late morning. An *irregular sleep-wake pattern* is described as largely disorganized sleep periods that do not follow a structured or synchronized routine. Irregular sleep patterns are normal for infants during the first few weeks of life. However, irregular sleep-wake patterns in children or adults signal a sleep disorder, often due to central nervous system disease (D'Cruz, & Vaughn, 2016).

Sleep Amount

Amount of sleep refers to the quantity of sleep an individual gets on a daily basis. Chronically getting too much or too little sleep can cause sleep disorders. *Inadequate sleep hygiene* is a disorder related to persistent failure to obtain adequate amounts of sleep (D'Cruz, & Vaughn, 2016). Individual characteristics that impact the quantity of sleep needed include age, activity level, and health (Hirshkowitz et al., 2015). In general terms, the amount of sleep required varies developmentally and incrementally decreases with age. On average, infants need 12 to 15 hours of sleep, toddlers need 11 to 14 hours of sleep, preschool aged children need 10 to 13 hours of sleep, school-aged children need 9 to 11 hours of sleep, teenagers need 8 to 10 hours of sleep, young adults and adults need an average of 7 to 9 hours of sleep, and older adults need an average of 7 to 8 hours of sleep health (Hirshkowitz et al., 2015). Inadequate sleep hygiene includes symptoms of fatigue and excessive daytime sleepiness, which diminish when an adequate amount of sleep is achieved.

Hypersomnia is a class of sleep disorders characterized by an overabundance of sleep. Narcolepsy is a primary sleep disorder that occurs when the brain loses its ability to regulate sleep-wake cycles and can mimic symptoms of inadequate sleep hygiene (D'Cruz & Vaughn, 2016). Narcolepsy, however, does not improve with adequate amounts of sleep and is a neurobiological disorder with hereditary characteristics. Narcolepsy causes symptoms of daytime tiredness. Sudden decreases in muscle tone that result in falls (cataplexy), sleep paralysis, and hallucinations may also be present (D'Cruz, & Vaughn, 2016).

Insomnia is a class of sleep disorders characterized by too little sleep (D'Cruz, & Vaughn, 2016) and related to central nervous system arousal. Insomnias are among the most commonly reported sleep disorders, affecting 10–15% of the population (Greenwalk & Sabini, 2016). Of reported insomnias, *psychophysiological insomnia* (anxiety-related sleep disruption often regarding sleep amount and quality) is the most common and accounts for 15% of all insomnias. *Sleep state misperception* (perceived delayed sleep onset and low sleep amount despite objective evidence of normal sleep onset and amount) is also prevalent and accounts for 5% of all reported insomnias (Fernandez, Eisenschenk, & Okun, 2009). Sleep insomnias, such as periodic limbic movement disorder (PLMD), have genetic dispositions and fragment sleep, significantly decreasing the sense of overall restfulness (D'Cruz, & Vaughn, 2016).

Sleep Quality

Sleep quality refers to the restfulness of sleep. Sleep disorders that cause abnormal sleep state transitions, including frequent arousal during sleep, lead to sleep fragmentation and a disruption of sleep structure (e.g. stages). Attempts to increase sleep amount do not provide

relief from symptoms of this class of disorders. An example of a sleep quality disorder is sleep apnea, a disturbance or restfulness caused by sleep-related respiratory disturbances (D'Cruz, & Vaughn, 2016). Sleep apnea impacts 1–2% of the general population (Fernandez, Eisenschenk, & Okun, 2009).

Biological Factors

Biological factors also cause sleep disorders. Predisposition for a sleep disorder may be rooted in genetic make-up. Women are more prone to sleep disorders including chronic insomnia (D'Cruz, & Vaughn, 2016). Sleep disorders with high familial influence include narcolepsy, obstructed sleep apnea (OSA), restless leg syndrome, insomnias, arousal disorders, enuresis, sleep terrors, and fatal familial insomnia (Fernandez, Eisenschenk, & Okun, 2009). Growth and life phases also impact susceptibility to sleep disorders, with older adults being among the most susceptible (Greenwalk & Sabini, 2016). Enuresis in children causes alterations in sleep patterns and impacts the susceptibility of sleep disorders. The incidence of nighttime enuresis is 30% of 4-year-olds, 10% of 6-year-olds, 3% of 12-year-olds, and 1–2% of 18-year-olds (Fernandez, Eisenschenk, & Okun, 2009). Children are also susceptible to sleep walking that can impact quality of sleep and disruption of the sleep-wake cycle. Of children in the general population, 10–30% engage in sleep walking (Fernandez, Eisenschenk, & Okun, 2009). Teenagers are also susceptible to difficulties with sleep phase disorders, specifically delayed sleep phase syndrome (D'Cruz, & Vaughn, 2016). Pregnancy is another factor contributing to the development of sleep disorders, with 11% of pregnant women experiencing restless leg syndrome (Fernandez, Eisenschenk, & Okun, 2009).

Environmental and Behavioral Factors

Environmental factors, including overcrowded housing, inadequate sleeping areas, noisy environments, and lack of adequate cooling or heating, increase susceptibility to sleep disorders. Use of electronics can impede sleep onset and light or noise from computer screens, cell phones, video games, and televisions may contribute to a predisposition to sleep disorders (D'Cruz, & Vaughn, 2016).

Other behaviors and routines also increase the likelihood of developing sleep disorders (D'Cruz, & Vaughn, 2016), including consumption of caffeine before bedtime, engaging in high stimulating activities, such as going to the gym within three hours of bedtime, and inconsistent sleep patterns (Greenwalk & Sabini, 2016).

Mental Health

Mental health disorders such as depression and anxiety, may contribute to development of sleep disorders. Mental health disorders may have hereditary and biological roots, or may be rooted in environmental and behavioral factors. Veterans suffering from posttraumatic stress disorder (PTSD) are among those with an increased likelihood of developing sleep disorders. Sleep disturbance is the most reported PTSD-related symptom among veterans (King et al., 2015).

Diagnosis

Sleep disorders are diagnosed via a detailed history of symptoms, family history of sleep disorders, and a thorough physical examination. Sleep diaries are frequently used to determine factors related to sleep quality and duration. Questionnaires facilitate accurate diagnoses (D'Cruz, & Vaughn, 2016). Polysomnography and hypnograms are also utilized in the diagnosis of sleep disorders. These objective diagnostic tests provide sleep data, including lights-out time, lights-on time, total sleep time, sleep latency (amount of time to fall asleep), REM latency (amount of time to enter REM sleep), wake after sleep onset, and sleep efficiency (Boghez & Mandruta, 2015). These data are useful in determining the presence and type of sleep disorder.

Treatment and Management

Treatment and management of sleep disorders often require multidisciplinary teams. Treatment must be individualized to account for individual characteristics, as well as specific features and causes of the disorder. Often, medical interventions are needed, including the use of respiratory aids or, in some cases, surgery. Sleep hygiene, medication, and psychotherapy are also used to manage sleep disorders (Greenwalk & Sabini, 2016). If another medical or psychological disorder is causing the sleep disorder, that disorder must also be treated in order to improve sleep and alleviate symptoms long term.

Sleep Hygiene

Sleep hygiene is a relatively nonintrusive method to treat and manage sleep disorders (Greenwalk & Sabini, 2016). Sleep hygiene includes stimulus reduction and behavioral techniques to modify maladaptive sleep patterns. This includes interventions such as avoiding caffeine, nicotine, and alcohol at night, exercising regularly in the afternoon but not within three hours of bedtime, avoiding naps, assuring accurate light and noise levels in sleep locations, getting up and engaging in a relaxing or boring activity when having difficulty sleeping, maintaining consistent bed and wake times, and avoiding going to bed hungry or eating heavy meals before bed (Greenwalk & Sabini, 2016).

Pharmacology

There are currently two classes of medications approved by the United States Food and Drug Administration (FDA) for treatment of insomnia related sleep disorders. This includes benzodiazepine receptor agonists and selective melatonin receptor agonists (Greenwalk & Sabini, 2016). Stimulant-based medications may be prescribed for treatment of daytime sleepiness and fatigue (D'Cruz, & Vaughn, 2016). Over-the-counter sleep aids, such as antihistamines, are readily available and may improve sleep onset and maintenance. However, there is little evidence supporting long-term sleep treatment with these medications. Herbs and home remedies, such as lavender, chamomile, and melatonin, are sometimes used as sleep aids despite few controlled studies supporting their effectiveness (Greenwalk & Sabini, 2016).

Psychotherapy

Behavior therapy can help to establish effective sleep routines and maintain structured sleeping habits. Behavioral therapy is also useful for practicing relaxation strategies and establishing calming pre-bedtime routines (D'Cruz, & Vaughn, 2016). Environmental therapy is useful in determining ideal sleep environments, including minimization of distractions and stimuli.

[1] *University of Texas at Arlington*
[2] *Riverside CA*

Chronic Pain: The Biopsychosocial Model

The *biopsychosocial model* is the most promising approach for conceptualizing the role that personality plays in chronic pain. Indeed, biopsychosocial interactive factors provide important information to more comprehensively assess and treat chronic pain (e.g. Gatchel, Peng, Peters, Fuchs, & Turk, 2007). To better understand the complex interactions between chronic pain and personality, the biopsychosocial model takes into account how core characteristics may predispose an individual to the onset of certain disorders, or provide resilience towards occurrence (Gatchel & Weisberg, 2000). The role of the environment can also either "buffer" or instigate psychopathology.

Does a Pain-Prone Personality Exist?

As earlier noted by Gatchel and Weisberg (2000), personality characteristics have not shown any direct effect on the acquisition of chronic pain. Therefore, the statement that *there is no one consistent "pain-prone personality syndrome"* (p. xi) is still true today. While it would be a much easier assessment to simply determine where a patient scored on a personality test, there is no evidence to support the existence of a primary or preexisting set of personality characteristics that are associated with the onset of pain. An individual's personality and psychosocial characteristics can, and frequently do, impact features of chronic pain, such as its severity and treatment (e.g., Cano-García, et al., 2013; Gatchel & Weisberg, 2000).

Non-Pathological Personality Characteristics

The goal of many comprehensive pain intervention programs is to manage rather than to cure pain (Gatchel, McGeary, McGeary, & Lippe, 2014). Thus, patients who implement more adaptive coping techniques are more likely to better manage pain and disability. Coping refers to an individual's specific cognitive and behavioral efforts to resolve and manage problems caused by chronic pain (Gatchel & Weisberg, 2000). Perceived control, locus of control, level of extraversion/introversion and perceived optimism are some of the personality characteristics that determine an individual's ability to successfully cope with stressors such as chronic pain (Gatchel & Weisberg, 2000; Taylor, 2015).

Perceived Control

As appropriately noted by Taylor (2015), perceived control (or the person's general sense of control over a particular situation or symptoms such as pain) can significantly decrease the emotional distress and disability associated with pain. For example, Mizener, Thomas, and Billings (1988) reported that, among patients successfully treated for "migraine headaches," there was a significant correlation between perceived control over psychological activity (via biofeedback training) and a reduction in headache activity. Overall, clinical research has revealed the important role of perceived control in reducing pain (Gatchel, et al., 2007).

Locus of Control

Related to perceived control is the concept of locus of control (LOC). LOC is considered internal if patients hold the belief that they have some degree of control over pain. Contrary to an internal LOC, individuals who show an external LOC would be more inclined to believe their pain is controlled by outside forces (e.g. surgical intervention) (Cano-García, et al., 2013). Individuals who express a stronger internal LOC utilize more adaptive coping strategies that result in less self-reported pain intensity, functional impairment, and emotional distress, relative to individuals who hold a primarily external LOC (Hamed, Raafat, Nasreldin, Abolmagd, & El Awar, 2012).

Introversion and Extroversion

It is not immediately obvious as to how an individual's level of extraversion-introversion might play a role in chronic pain, but extensive research outcomes have shown numerous relationships. Extraverted patients are more likely to complain about pain but show a higher pain tolerance than more introverted patients (Gatchel & Weisberg, 2000; Park, Lee, Sohn, Eom, & Sohn, 2014). This phenomenon may be attributed to extraverts having lower amounts of the excitatory neurotransmitters (e.g., acetylcholine) than introverts, resulting in introverts having an overstimulation of sensory impulses that occur in the experience of pain (Lester, 1989). Additionally, extraverts exhibit a lower psychosocial response to pain, resulting in fewer feelings of sadness (Park, et al., 2014). Furthermore, introverted patients are at higher risk for social isolation and depression, which are associated with greater pain sensitivity (Gatchel & Weisberg, 2000). It has also been suggested that extraversion-introversion should be viewed as consisting of several covariates that influence pain reactivity and prognosis (e.g. social isolation) (Gatchel & Weisberg, 2000).

Optimism

Perceived optimism affects many health outcomes, such as increasing positive symptom reports, predicting recovery time after surgery, and reducing the toll that chronic pain can inflict on everyday activity (Powell et al., 2012; Taylor, 2015). For instance, Boselie and colleagues (2014) found that reinforcing optimism to a group of participants attenuated the deteriorating effect of pain on executive-task performance. Indeed, restoring executive-task performance in patients with chronic pain may reduce the negative effect of chronic pain on daily functioning. Optimism can also affect the onset of chronic pain. For example, Powell and colleagues (2012) found that presurgery levels of optimism independently predicted pain intensity and chronicity at four months. The findings of Powell et al. (2012) support the implementation of psychosocial interventions to reduce the risk of pain becoming chronic. Such studies reflect a growing emphasis on optimism in the chronic pain literature.

Pathological Personality Characteristics, Chronic Pain, Treatment Implications

As with nonpathological personality characteristics, pathological characteristics impact an individual's ability to cope with chronic pain and related stressors. Fear-avoidance beliefs, negative affect, and pathological personality characteristics are some of the factors that impact an individual's ability to cope with pain (Arts et al., 2015).

Fear Avoidance and Pain Catastrophizing

The *Fear-Avoidance Model* of chronic pain has historically been a dominant model, integral to the understanding of how chronic pain is established and maintained (Wong et al., 2014). As reviewed by Gatchel and Neblett (2015), *pain catastrophizing* is a precursor to fear-avoidance behavior. Indeed, if one begins to interpret pain as especially harmful and threatening, and then begins to catastrophize about it (e.g. "I worry all the time about whether the pain will end."), then a negative cascade of emotions and cognitions about the actual or anticipated pain is likely to occur. This may result in overmonitoring and hypervigilance of bodily sensations, which can lower pain threshold. Thus, the *Fear-Avoidance Model* is based on the interaction of pain catastrophizing (the negative appraisal of pain) and the development of pain-related fears, which promote avoidance behaviors (Gatchel & Neblett, 2015).

Negative Affect

Pathological personality factors interact with environmental variables to mediate the perpetuation of pain, and the transition from acute to chronic pain (Brox, Storheim, Holm, Friis, & Reikeras, 2005; Campbell, Clauw, & Keefe, 2003). Thus, identifying pathological personality factors related to chronic pain may lead to the development of interventions specifically targeted at chronic pain prevention. Correspondingly, depression

is moderately related to pain indices and shares biological pathways (such as mono-amine neurotransmitters) with pain (Blair, Robinson, Katon, & Kroeuke, 2003). Marsala and colleagues (2015) lend support to the assertion that common structures (i.e. limbic areas) and neuronal pathways are involved in the onset of both depression and pain. The association between depression and physical pain again highlights the importance of adopting a biopsychosocial approach to fully understand, prevent, and treat chronic pain.

Personality Disorders

Individuals with a personality disorder (PD) often experience impairment in social and occupational functioning and are unable to cope with major stressors such as chronic pain (Trull & Kearney, 2012). Indeed, the presence of a PD or cluster of pathological personality traits can impair the coping ability of chronic pain patients. This finding is highly salient for chronic pain populations, with past research demonstrating a robust relationship between chronic pain conditions and personality disorders (PDs) (Conrad, Wegener, Geiser, & Kleiman, 2013). High rates of comorbidity between PDs and other disorders (e.g., depression), are also important to consider when treating chronic pain (Gatchel, et al., 2014).

Borderline Personality Disorder

The types of PDs that have been found to be associated with chronic pain vary for a number of reasons. Conrad and colleagues (2007) observed that paranoid personality disorder (PPD) and borderline personality disorder (BPD) were the two most commonly reported PDs among a sample of chronic pain patients, whereas Fischer-Kern and colleagues (2011) reported obsessive-compulsive disorder and BPD as the two most diagnosed PDs in a sample of patients with chronic pain. The high suicide rate associated with BPD (approximately 3–10% of individuals with BPD commit suicide by age 30), and the propensity for self-harm, have caused an explosion of research aimed at investigating the complex relationship between BPD and pain (Trull & Kearney, 2012).

Conclusion

Patients suffering from chronic pain report an array of problems (Gatchel, et al., 2007). Acceptance of the biopsychosocial model of pain has resulted in a proliferation of interdisciplinary treatments that address individual patient needs. Interdisciplinary pain management programs typically consist of physical and/or psychosocial interventions that are intended to decrease disability and pathological factors associated with pain, as well as to increase coping capacity and quality of life (Van der Maas et al., 2015). Interdisciplinary treatment can include a number of different modalities, arranged in a number of different combinations according to individual needs and biopsychosocial characteristics (e.g. personality traits).

Personality and Sexual Dysfunctions

David L. Rowland and Aaron R. Tempel

Valparaiso University

Psychologists have long sought a link between various personality characteristics and a propensity toward sexual dysfunctions, particularly those dysfunctions having a psychological (rather than organic) basis. Such links might not only help predict vulnerability toward particular sexual problems but also provide insight into the problem and suggest particular treatment strategies. Although moderate success has been achieved in drawing associations between personality and sexual function, simple, strong, and clear etiological relationships have, for the most part, eluded psychologists. In this entry, we first identify the sexual dysfunctions, then elaborate on "personality" as a psychological construct, providing a framework for the present discussion.

Sexual dysfunctions are disorders involving the disruption of the sexual response cycle. Traditionally, the sexual response cycle involves three elements: desire, arousal, and orgasm, with dysfunctions tied to any one or more of these phases. Classification of these dysfunctions using the *Diagnostic and Statistical Manual of Mental Disorders*, fifth edition (DSM-V) is differentiated by sex. Thus, male hypoactive sexual desire disorder, erectile dysfunction, premature ejaculation, and inhibited ejaculation denote male sexual dysfunctions whereas female sexual interest/arousal disorder, female orgasmic disorder, and genito-pelvic pain/penetration disorder denote female sexual dysfunctions. Biological, psychological, and relationship factors can affect both the onset and maintenance of these dysfunctions. Personality characteristics appear to be one among many psychological factors that serve as risk factors for sexual dysfunction.

Personality refers the enduring pattern of emotions, thoughts, and behaviors that an individual expresses in his/her daily interactions. These patterns interact with the immediate emotional, cognitive, and general psychological demands of the moment. Personality traits are descriptive in nature – providing a unified conceptualization of a set of psychobehavioral characteristics that typically occur in concert with one another. In this entry, three personality-based topics are discussed: personality traits, personality-related factors, and psychopathologies. However, important to note is that personality characteristics themselves do not determine sexual problems; rather the constellation of attitudes,

emotions, thoughts, and behaviors that comprise a specific personality descriptor may place an individual at greater risk for a sexual problem.

Personality Traits

A number of personality traits appear to have a fairly straightforward relationship to sexual arousal, pleasure, and dysfunction. Although such traits may contribute to sexual enjoyment or sexual problems, they typically represent one of many factors impinging on sexual response at a given time for a given individual with a given partner. That is, certain personality characteristics, combined with relational and situational factors, may contribute to or detract from the sexual experience. As such, these traits typically play a secondary, perhaps exacerbating or intensifying, role in sexual response and enjoyment – they are seldom viewed as a primary cause for a sexual problem; rather, an individual having such dispositions may bring specific vulnerabilities and/or strengths to situations involving sexual intimacy.

Negative trait affect is characterized by an individual's heavy focus on negative emotions (e.g. anger, anxiety, and guilt); positive trait affect is characterized by an individual's focus on positive emotions (happiness, enthusiasm). Trait affectivity has been implicated in sexual dysfunction. For example, women with higher positive trait affect report higher levels of sexual desire, arousal, and satisfaction. And the pleasure derived from satisfying sexual experiences may further enhance their sexual desire and arousal. In contrast, negative trait affect is associated with problems surrounding sexual functioning, including vaginismus (sexual pain). Likewise in men, negative trait affect is correlated with diminished arousal and erectile functioning. Thus, the general tendency to experience life negatively may well affect one's perception and evaluation of sexual encounters, thereby negatively affecting various components of sexual response.

Related to negative trait affect, neuroticism is a personality trait characterized by nervousness, fear, worry, and emotional instability. High levels of neuroticism have been associated with male sexual dysfunctions. Neurotic tendencies may prompt negative feelings and thoughts; therefore, when sexual issues arise (such as premature ejaculation), a man higher in neuroticism is likely to evaluate himself negatively. In women, greater emotional instability is correlated with increased risk of orgasm difficulties. Specifically, women who fluctuate between positive and negative emotional states may come to associate sex with negative emotionality which, over time, may be manifested in a sexual difficulty. Such patterns of negativity may affect sexual performance by setting up negative expectations (and negative self-efficacy) in future encounters.

Hostility, irritability, and aggressiveness are personality traits implicated in both male and female sexual dysfunction. In women, hostility has been related to sexual pain and irritability, with ensuing problems in reaching orgasm. Additionally, anger is known to interfere with women's sexual desire and arousal, opening the possibility of arousal/desire disorders. In men, agitation appears to be connected to premature ejaculation, although a clear explanation of an underlying process is lacking. But in general, such personality traits may lead to altered perceptions towards sex which become self-perpetuating: the predisposition serves as a risk factor for the sexual problem, while the sexual failure strengthens the predisposition.

Extraversion-introversion (E-I) may play a role in sexual enjoyment and dysfunction. E-I is a characteristic that denotes the source of the person's psychological, emotional, and (even) physical energy: extraverts gain energy from being around others while introverts gain energy from time spent alone. Introverts may also find social interactions emotionally draining. Therefore, it stands that difficulty experiencing orgasm has been associated with increased levels of introversion. Although introversion in and of itself does not lead to sexual problems, an individual may come to avoid sex due to its emotionally taxing nature. In contrast, extraversion is positively correlated with male sexual functioning, possibly from the fact that such men may feel energized by their interactions with other people, including their partner.

Openness, a trait related to willingness to try new experiences and a general curiosity about life, has been implicated in sexual dysfunction in both men and women. Low openness has been related to orgasmic problems in women and erectile/arousal problems and inhibited ejaculation in men. A low level of openness may result in negative attitudes about sex or may limit an individual's willingness to expand his/her sexual attitudes and behaviors.

Other personality traits may affect sexual functioning, but their impact is less clear and/ or consistent. For example, the relationship between conscientiousness (carefulness and thoughtfulness) and agreeableness (warmth and empathy) on the one hand, and sexual dysfunction on the other, is mixed. Generally, they may contribute to the enjoyment of sexual experiences for some; and those who are low in these dimensions may feel less connected with their partner and therefore more vulnerable to a sexual problem.

Personality-Related Factors

Personality-related factors represent predominating psycho-behavioral patterns within an individual, but they are not seen as enduring and consistent as traits – that is, they represent perceptions and thought patterns that are more likely to be influenced by situation and experience. However, these factors are often affected by overlying personality characteristics. For example, schemas – processes of thought that organize and create relationships between information – appear to be influenced by personality. The intersection of personality characteristics and specific schemas may be responsible for sexual problems in some men and women. For example, women who typically experience higher levels of incompetence, loneliness, and fear are more likely to have desire deficits, orgasm difficulties, and vaginismus than other women. One way in which schemas may act is by altering sexual attitudes, which thus affect sexual functioning. Some such attitudes may stem from religious, cultural, or generational views (e.g. association of sexual pleasure with guilt) and have strong potential to affect desire and arousal, particularly in women.

Self-esteem (the evaluation of one's worth) and self-efficacy (a person's confidence of being able to achieve a desired end point) are important factors contributing to sexual response and dysfunction. Self-esteem is often connected to self-consciousness, including awareness of one's body (body image). Owing to the emphasis on attractiveness at both the cultural and interpersonal levels, low body image, self-esteem, and self-efficacy may interact in ways that interfere with healthy sexual response. For example, in women, negative body beliefs and low body image are related to higher incidences of orgasmic dysfunction; in men, negative body image, low self-esteem, and high self-consciousness are related to erectile dysfunction.

Anxiety, a transient state distinguished from the longer-lasting anxiety *disorders* (see below), is often tied to demands to perform sexually. Partnered sexual activity, particularly early on in relationship, has both evaluative and consequence components: each person may be concerned about his/her partner's expectations and perceptions, and each may worry that if performance is not "adequate," then not only does embarrassment and shame follow, but the partner's evaluation of the situation may have implications for the relationship itself. Although such anxiety tends to be specific to the sexual situation, vulnerability to feelings of high anxiety may be an inherent characteristics among some individuals. For example, a high level of anxiety may interfere with the normal erectile process in men and both arousal and orgasmic response in women.

Psychopathologies

Psychopathologies refer to mental disorders that lead to significant impairment in carrying out one's daily activities, including interactions with other people. Although considered distinct from personality, they have the potential to affect personality, and personality has the potential to increase the likelihood of specific psychological disorders – that is, psychopathologies and personality variables are often interconnected. Furthermore, some psychopathologies are known to affect sexual functioning.

Anxiety disorders, as with situational anxiety discussed above, may lead to sexual problems. For example, trait anxiety and nervousness have been related to orgasmic dysfunction and sexual pain in women, with the latter likely acting reciprocally on orgasmic function. Anxiety and general vulnerability are also found to be higher in men with sexual dysfunction than non dysfunctional men. The experience of anxiety surrounding sexual activity may shape sexual attitudes and expectations that exacerbate existing or developing sexual difficulties.

Similar to trait-related anxiety, social phobia, characterized by intense anxiety elicited from social situations, is moderately related to premature ejaculation. Such individuals may respond negatively to the overwhelming pressures (both cultural and partner-based) to perform adequately during sex.

Depressive disorders are strongly related to sexual problems. These disorders manifest as depressed or sad mood, sleep dysfunction, anhedonia, fatigue, and suicidal thoughts. Depression has been related to problems occurring in all phases of the sexual response cycle – desire, arousal, and orgasm – in both men and women. Depression may impact sexual functioning by reducing pleasure, lowering self-efficacy, and inhibiting positive emotions.

General Interpretation and Conclusion

Broadly speaking, sexual response represents a balance between excitatory and inhibitory processes. To the extent that certain personality characteristics or psychopathologies interfere with or mitigate arousal/excitatory processes, they will tend to affect sexual response negatively. Thus, negative affect-anxiety, strong introversion, high hostility, and low openness have the potential to decrease sexual enjoyment and pleasure, as well as to increase the likelihood of sexual problems. In many cases, a negative predisposition may represent both/

either a risk factor, increasing the probability of a particular outcome, and/or a consequence, with the sexual problem intensifying an already existing condition or predisposition.

At the same time, certain positive characteristics are likely to enhance excitement, sexual enjoyment, and satisfaction. These positive experiences increase positive attitudes toward sexuality and lead to positive expectations and self-efficacy surrounding sexual intimacy. Persons experiencing sexual problems may often benefit from counseling that helps them change cognitive frameworks and/or alter emotional tendencies counterproductive to rewarding sexual experiences. However, in those instances in which significant psychopathology exists, treatment of the psychological disorder precedes treatment of the sexual problem, as the sexual problem is typically secondary to the psychological problem.

Although research on the intersection between personality and sexual dysfunction has yielded some insights into sexual dysfunction, future research will not only need to operationalize personality variables with greater precision, but also better define the underlying psychological and physiological processes through which the one affects the other.

Paranoid Personality Disorder

Keri Ka-Yee Wong

University of Cambridge

Definition

Paranoid personality disorder (PPD) is one of three Cluster A personality disorders (schizoid and schizotypal personality disorders being the others) characterized by pervasive distrust and suspiciousness of the motives of others (DSM-V, 2013). Classified under specific personality disorders in the ICD-10 (World Health Organization, 2016), an individual qualifies for a diagnosis with PPD when the criteria for general personality disorder are met, plus at least three of the following:

1) Excessive sensitivity to setbacks;
2) Persistent unforgiveness of insults;
3) Suspiciousness and pervasive distrust, misinterpreting the actions of others as malevolent and hostile;
4) Recurrent suspicions, without justification, regarding the sexual fidelity of the spouse or sexual partner;
5) Combative and tenacious sense of personal rights;
6) Excessive self-importance and self-reference;
7) Preoccupation with unfounded conspiratorial explanations of events happening to the individual and in the world at large.

The diagnosis includes expansive paranoid, fanatic, querulant, and sensitive paranoid personality (disorder) but importantly, excludes paranoia as a delusional and psychotic disorder as seen in schizophrenia. In summary, PPD a nonpsychotic disorder wherein the diagnosis is based on one's maladaptive personality traits, not that of a mood or thought disorder, with the key distinction from schizophrenia being that individuals with PPD do not suffer from hallucinations.

Epidemiological studies in the last three decades have reported prevalence rates of 2.3–4.4% for PPD and found that PPD is often comorbid with alcohol and substance use disorders. Research examining PPD across cultures is limited. One meta-analytic study

(McGilloway, Hall, Lee, & Bhui, 2010) has documented the prevalence rates for personality disorders in different ethnic groups showing comparable results between Asians, Hispanics, and Whites and more variation between Blacks and Whites, although effects may be largely attributable to the heterogeneity in the methodology reflecting the need for more cross-cultural research on PPDs in general.

In terms of heritability, a large Norwegian study of 1,386 twins (Kendler et al., 2006) found PPD to be moderately heritable (28%) and to share a portion of its genetic risks with other Cluster A personality disorders (43%). No evidence from this study supported shared environmental or sex effects for these PDs. Similarly, another morbidity study found higher prevalence rates of PPD in males than in females; however, this difference was not statistically significant (Singleton et al., 2000).

Paranoia specifically, has been found to vary along a continuum of severity; affecting patients on the severe end of the spectrum as well as 10–15% of young adults in the general population. More recent developmental studies of children and adolescents have also extended certain adult models of paranoia to childhood suspiciousness, replicating the positively skewed distribution of many children reporting few suspicions, while few children report many suspicions (Wong, Freeman, & Hughes, 2014; Zhou et al., 2018). Even though more work needs to be conducted to clarify the unfounded nature of these beliefs, there is initial evidence favoring a 'social explanation' to childhood paranoia and that examining suspicions developmentally may be beneficial in understanding the etiology of paranoia, as well as its other symptoms (Wong, 2015; Wong & Raine, 2018). Factor analytic studies have demonstrated that paranoid ideations overlap with other forms of delusions, although they are also found to be distinct and hence worth studying in their own right.

Assessment

There are many diagnostic issues with PPD. While a certain level of suspiciousness may be evolutionarily advantageous and considered a normal response to stress, it is a clinicians' job to verify that a patient presenting with paranoid thinking is distinct from patients with other personality disorders such as depression and anxiety, schizophrenia, and other psychotic disorders. This has important implications on the prognosis, treatment, and even criminal offending as PPD is often implicated with aggression and violence (Carroll & McInerney, 2015). Thus, it is important for clinicians to not just diagnose the patient with the presence or absence of symptoms, but to work with the patient to understand the content of their suspicions.

The distinction between PPD and delusional disorders is particularly challenging, especially when individuals who lack trust in others are less likely to seek help. Currently, assessments of PPD are based on self-report questionnaires such as the Paranoia scale of the Personality Assessment Inventory (PAI; Morey, 2007), structured interviews such as the Structured Clinical Interview for DSM Disorders (SCID-5-PD; APA, 2015) and the International Statistical Classification of Diseases and Related Health Problems 10th Revision (ICD-10; WHO, 2016). More recently, brief screening interviews for clinical samples such as the Standardized Assessment of Personality – Abbreviated Scale (SAPAS;

Moran et al., 2003) has also been found to moderately correlate with traditional assessments of personality disorders. However, the initial step to seeking help is still an ongoing challenge for many individuals suffering from PPD.

One prevailing difficulty in paranoia research is determining whether the ideation is unfounded, which until recently, this question had remained unresolved. To begin addressing this gap, moment-to-moment virtual reality (VR) paradigms enabling individuals suffering from phobias and paranoia to interact with benign avatars in controlled virtual environments followed by pre- and post-experiment psychosocial questionnaires and interviews have shown promising results. Specifically, in paranoia research, any paranoid responses are recorded as unfounded since VR environments are programmed to be neutral. Empirical studies to date have begun to support VR exposure as an effective research and clinical tool to understanding and improving the lives of individuals with mental health disorders.

Causes

The causes of PPD are complex and consideration of both social and cognitive factors have made substantial progress in research on paranoia. This body of evidence stems primarily from studies of patients with persecutory delusions and young adults with high levels of paranoid ideations.

The *Attribution-Self-Representation Cycle* (Bentall et al., 2001) provides a social understanding of paranoia and states that an individual's attribution to agents and events is intricately linked with their representation of the self, which, in turn, shapes future attributions. The individual constructs beliefs in order to cope with discrepancies between how others view them and how they would like to be viewed (primarily to defend against their self-esteem). Studies have shown that individuals with low self-esteem tend to make internal attributions for negative events, whereas individuals with high self-esteem and low depressive symptoms tend to attribute success to internal factors and negative events to external causes. Whether attributional style functions to defend against low self-esteem or whether it is specific to persecutory delusions or other types of delusions has been contested, as intervention studies showing improvement in persecutory delusions through therapy demonstrated unchanged levels of depression and self-esteem. This therefore suggests that persecutory delusions do not serve the function of defense but perhaps as a more general reflection of the individual's emotions. More recent work from Bentall et al. (2012) has also demonstrated a dose-response relationship between each increase in symptoms of early childhood adversity (e.g. physical/sexual abuse, victimization, separation from the home) and the risk of paranoia. In particular, controlling for comorbid hallucinations, growing up under institutional care was found to increase the odds for paranoia by 11 times. This lends support to the case that early childhood adversity may initially seem "rational," and may predispose an individual to paranoid thinking and schizophrenia-like symptoms (Wong & Raine, 2019).

Contrasting the social perspective is the *Threat Anticipation Model* (Freeman et al., 2002), which highlights the interaction between affective reasoning and anomalous experiences as a trigger for delusional experiences. In this model, major stressors, insomnia, and drug

abuse can "trigger" both abnormal internal experiences (cognitive biases) and external events (discordant negative social experiences). The theory also accounts for existing levels of emotion (e.g. anxiety, self-belief, and cultural schemas) and reasoning (e.g. confirmation bias and reasoning bias) during paranoia as factors that may fuel the individual's behavior, such as rumination and withdrawal from social interactions. The interplay between these factors results in persecutory threat beliefs. Studies of patients with persecutory delusions have demonstrated that patients with delusions are more likely than nondelusional individuals to respond in a biased manner (i.e. jump-to-conclusions).

Treatment

Currently, there are no established treatment recommendation for PPD. Cognitive behavioral therapy (CBT), typically provided weekly for at least six months, has been shown to be effective for patients with delusions and hallucinations. Approximately 20% of patients with persistent delusions respond well to the treatment and another 40% showed improvements. Although CBT may be less effective for individuals distressed by their paranoid experiences, recovery time has been shortened in those with acute psychosis and relapse rates reduced in few cases. Patients with cognitive deficits and the lack of insight into their illness are not precluded from CBT treatment. Recent randomized controlled experimental studies have demonstrated that patients may relearn "fearful" situations under the neutral conditions of a virtual social environment. Compared to patients with mere VR exposure, patients in the VR cognitive therapy environment who were taught strategies to challenge their fears in benign social environments reported 22% and 19.6% reduction in delusions of conviction and real-world distress, respectively (Freeman et al., 2016). Although there are just a handful of RCTs using VR, cognitive therapy through VR paradigms show promise and may prove effective in treating paranoia (d=1.3) and perhaps, other mental illnesses (e.g. anxiety) (Freeman et al., 2017). There are also no FDA approved medications to treat this disorder.

Conclusions

The inherent beliefs of distrust in others can be both exhausting and debilitating for individuals with PPD and those around them, not to mention the added difficult for individuals to seek help. New technology such as VR paradigms together with psychotherapy components may be promising new tools for research as well as treatment for individuals with PPD. On balance, this literature highlights the need to develop more effective and targeted intervention initiatives for personality disorders in general.

Schizoid Personality Disorder

Daniel J. Winarick

Queens College–City University of New York

Diagnostic Classification

Schizoid personality disorder (SZPD) is defined in the fifth edition of the *Diagnostic and Statistical Manual of Mental Disorders (DSM-V)* published by the American Psychiatric Association (APA, 2013) as a maladaptive, longstanding tendency towards social isolation, withdrawal, and detachment that is present in a variety of settings and impairs occupational, social, or psychological functioning. It is classified as a personality disorder (PD) by the DSM-V (APA, 2013), and its symptoms include the lack of desire for family involvement, a preference for solitude, having few friendships, minimal – flat or restricted – emotional expression, and experiencing decreased pleasure from sexual as well as physical activity. Per DSM-V (APA, 2013), to be diagnosed with SZPD, at least four of the following six diagnostic criteria must be present: (1) preference for solitary activities, (2) lack of interest in and absence of close or family relationships, (3) lack of interest in sexual relations with another person, (4) absence of pleasure from physical activities, (5) apathy in response to external evaluations and judgments, and (6) interpersonal affective disengagement. SZPD has been conceptualized in a variety of ways, but its hallmark features of isolation, detachment, and withdrawal have remained consistent across theoretical perspectives and throughout its history.

The construct of SZPD was originally a broad construct, consisting of emotional sensitivity and anxiety in addition to detachment. However, in the DSM-III (APA, 1980) it was redefined (Livesley, West, & Tanney, 1985). Subsequently, the SZPD construct that has been included in each subsequent edition of the DSM is essentially defined by social isolation and emotional detachment. Extant criticism of the validity of this definition of SZPD can be found in the clinical and empirical literature (e.g. Livesley et al., 1985; also, see Ahktar, 1987). The proposal for an Alternative Model for the Dimensional Classification of Personality Disorders explicitly removed it from the list of diagnosable PDs. Several recent empirical studies and reviews have echoed the view that SZPD lacks construct validity (e.g. Hummelen, Pedersen, Wilberg, & Karterud, 2015). However, other research has found

empirical support for the DSM-V (APA, 2013) conception of the SZPD in connection to identifying its core underlying dimensions as social anhedonia and low empathy (Winarick & Bornstein, 2015).

Historical Views: From Antiquity to Descriptive Psychiatry and Psychoanalysis

References to isolated, detached, and withdrawn individuals were evident as far back as antiquity in literature and medical science. Extant literature has credited Hippocrates and Galen with the first account of the SZPD construct by linking isolation, detachment, and withdrawal with a bodily substance called a "humour" and labeled phlegm as the "phlegmatic temperament type." Around the late nineteenth century and early twentieth century, historical precursors to the construct of SZPD emerged in the fields of descriptive psychiatry and psychoanalysis. While psychodynamic theorists generally focus on internal dynamics and descriptive psychiatrists highlight observable symptom clusters, both schools of thought ended up with a description of a common personality type that dovetails with the observable features of the DSM-V (APA, 2013) categorical definition of SZPD. Descriptive psychiatry, including Kraepelin, Hoch, Bleuler, and Kretschmer depicted individuals with SZPD as isolated, socially withdrawn, and emotionally detached (see Livesley et al., 1985 for a review). However, they also emphasized the intense inner sensitivity of individuals with SZPD or at least highlighted the enigmatic nature of their subjective experience in contrast to the DSM-V (APA, 2013). Descriptive psychiatry linked SZPD to schizophrenia both genetically and phenomenologically by noting that it was often observed in the biological relatives of individuals with schizophrenia as well as in individuals who later went on to develop schizophrenia (for a review, see Meehl, 1962).

A central difference between the psychoanalytic and the DSM viewpoint is that the former views schizoid detachment as a defense that masks intense, over stimulating, and painful emotional experience (e.g. McWilliams 2005; Ahktar 1987), whereas the latter views the overt presentation of the schizoid person as reflecting a genuine lack of desire for social relationships accompanied by social-cognitive deficits.

Ahktar (1987) pointed out that Freud's concept of the "narcissistic personality" corresponded closely with present-day conceptions of schizoid individuals, understood as an inwardly directed libido (see e.g. Ahktar, 1987). Per Millon & Davis (1996, p. 45), Freud explained the schizoid psychic structure in terms of a weak, inhibited, or lacking super-ego and id in contrast to their overly developed and active ego. The Freudian perspective has viewed schizoid personality disorder as (a) indifference towards others and a lack of social connectedness (i.e. in the context of their inactive super-ego); (b) lack of aggressive or sexual urges (in connection to their lacking id); and (c) excessive concern with internal experience, thoughts, and imagination (in the context of their over-active ego) (see Millon & Davis, 1996, p. 45).

Wilhelm Reich viewed social isolation in schizoid individuals as a characterological defense mechanism against threatening and destabilizing, sexual and aggressive drives (Silverstein, 2006, p. 46). Reich also identified depersonalization as characteristic of the

schizoid personality type, highlighting their lack of connectedness to the external world and other people. Millon and Davis (1996, p. 222) reported that Deutsch indicated that schizoid individuals possessed an "as-if" personality in which they go through the motions of life without feeling connected to anyone or anything, in a sense acting in ways that they know are appropriate but without any genuine feelings underneath.

Silverstein (2006) held that schizoid interpersonal detachment could result from an intense subjective emptiness rather than as a defense against overwhelming drives. Silverstein (2006) reported that Melanie Klein viewed schizoid isolation as a primitive, regressed state of being in which splitting predominates (see Ahktar, 1987, for a review). Klein hypothesized that schizoid individuals withdraw, detach, and isolate because of their split object representations (i.e. they project the dangerous, threatening, and persecutory – in other words, aggressive – aspects of themselves onto others to maintain a positive, sustainable view of the self), which results in the perception of being dangerous, threatening others that need to be kept at a distance (Ahktar, 1987; Silverstein, 2006).

More recently, British object-relational views of SZPD, such as Guntrip (1969), see solitary, disconnected, and emotionally cut-off lifestyles as the product of maternal deprivation during early childhood that resulted in them equating relationships with emotional pain and traumatic experience, seeing others as persecutory. Guntrip (1969) identified the need to escape from external reality into one's thoughts, fantasies, or subjective reality as a core characteristic of the schizoid character structure. He viewed this need as stemming from intense fears of mental collapse in the context of primitive, unmet needs for safety and nurturance, as well as the perception of a frightening and daunting environment (Guntrip, 1969, p. 87).

Psychometric Trait-Based Conceptions

SZPD has been conceptualized from the perspective of the Five Factor Model (FFM) of personality as comprised of abnormal and maladaptive proportions of normal personality traits. Specifically, SZPD has been conceptualized by the FFM as (1) low extraversion (high introversion), a factor consisting of (a) low warmth, (b) low gregariousness, (c) low assertiveness, (d) low activity, (e) low excitement-seeking, and (f) low positive emotions as well as (2) low openness to experience, commonly referred to as low O. The FFM definition of SZPD as low E and low O has largely been confirmed by empirical research (Widiger, Trull, Clarkin, Sanderson, & Costa, 2002).

Another multitrait model of PDs is the Interpersonal Circumplex Model (IPC), which classifies PDs along two perpendicular *X* and *Y* axes that represent opposing pathological personality traits, respectively. The horizontal *X*-axis spans the dimension commonly labeled *love* ranging from coldness to warmth; whereas, the vertical *Y*-axis spans the dimension of *assertiveness* ranging dominance to submissiveness. From the perspective of the IPC, SZPD has been described as low in warmth and high in coldness as well as low in dominance and high in submissiveness. Wiggins & Pincus (2002) demonstrated empirical support for the IPC conception of SZPD using factor-analytic methods: SZPD loaded on what they labeled the "aloof-introverted" quadrant of the IPC, which is defined by "unassured-submissive" and "cold-hearted" traits.

In addition to the IPC and FFM, attachment theory also accounts for SZPD in connection to trait dimensions. Attachment theory originally proposed categories or types of attachment but has more recently psychometrically defined two distinct attachment dimensions, namely attachment avoidance and attachment anxiety using a scale called the Experiences in Close Relationships (ECR). Based on relative levels of attachment avoidance and attachment anxiety, four basic attachment categories can be formed: high anxiety/high avoidance (anxious-avoidant attachment), high anxiety/low avoidance (anxious-preoccupied attachment), low anxiety/low avoidance (secure attachment), and low anxiety/high avoidance (dismissing-avoidant attachment). SZPD is characterized by a dismissing-avoidant attachment style; in other words, low in attachment anxiety and high in attachment avoidance (Meyer, Pilkonis, & Beevers 2004).

Clinical Cognitive Perspective

Beck et al. (2004) reported that individuals with schizoid PD typically have a history of being teased, bullied, and rejected by their peers as well as feelings of alienation. In addition, they have a negative view of self and others as well as relationships (Beck et al., 2004). Furthermore, Beck et al. (2004) held that these individuals disengage from the world and lead solitary lives out of their dysfunctional beliefs about obtaining "safety." Beck et al. (2004) identified the following core beliefs characteristic of individuals with schizoid PD: "I am different ... I am a loner ... I am nothing ..." (p. 143). Beck et al. (2004) also noted that prototypical individuals with schizoid PD generally express symptoms of anxiety during social interactions but it is in the absence of any fears of criticism. Individuals with schizoid PD reportedly describe frequent experiences "of being overwhelmed by social contact ..." when they have too much interaction with others (Beck et al., 2004, p. 143). Beck et al. (2004) also reported diminished expression of affect and a tendency toward depressed mood in connection to existential concerns as core clinical features of schizoid PD.

Histrionic Personality Disorder

Gregory J. Lengel

Drake University

Conceptualization and Features

The fifth edition of the *Diagnostic and Statistical Manuel of Mental Disorders* (DSM-V; American Psychiatric Association, 2013) defines histrionic personality disorder (HPD) as "a pervasive pattern of excessive emotionality and attention seeking" (p. 667). For one to receive this diagnosis, he or she must meet criteria for a personality disorder, as well as demonstrate at least five of eight HPD-specific symptoms: (1) discomfort when not the center of attention, (2) inappropriate sexually seductive or proactive behavior, (3) rapidly shifting and shallow emotional expressions, (4) use of physical appearance to draw attention to oneself, (5) speech that is impressionistic and lacking in detail, (6) self-dramatization, theatric, and exaggerated emotional expression, (7) suggestibility/being easily influenced by others, and (8) a tendency to consider relationships to be more intimate than they are in reality. Commensurate with other personality disorders, the pattern of inner experience and behavior must be inflexible, pervasive, and stable, deviant from cultural expectations, and lead to significant distress or impairment in daily functioning.

Individuals with HPD characteristically experience significant dysfunction to their social, occupational, and personal functioning, such as difficulty sustaining relationships, poor interpersonal reliability, erratic employment history, potential inappropriate romantic/sexual involvement with colleagues, impulsivity, affective instability. Furthermore, individuals with prototypic HPD features can be overly reactive and novelty seeking, and are perceived by others as overly dependent, demanding, shallow, high strung, and high maintenance (Beck et al., 2004). Individuals with HPD also tend to struggle with delaying gratification as well as have a proclivity to be emotionally manipulative. In regard to common comorbidities, individuals with HPD demonstrate elevated rates somatic and conversion disorders, major depressive disorder, as well as comorbid personality disorders, including borderline personality disorder, narcissistic personality disorder, antisocial personality, and dependent personality disorder. Further, similar to persons with borderline

personality disorder, individuals with HPD have a tendency to engage in suicidal threats and gestures in effort to gain attention or coerce others.

Prevalence, Etiology, and Course

HPD has been estimated to occur in 1–3% of the general population, and upwards of 24% of clinical samples (Blashfield & Davis, 1993). However, there is much variability in reported prevalence rates, leading to disagreement regarding HPD's actual prevalence. Little is known about the etiology and development of HPD. However, heritable factors, such as genetics and personality traits (e.g. elevated extraversion and neuroticism) appear to play a significant role. Additionally, HPD might also be influenced by environmental factors, such as early familial reinforcement of attention-seeking behavior. Little is also known regarding premorbid behaviors among individuals who will later develop HPD. However, during adolescence, such individuals are likely to act in an attention-seeking, flamboyant, and flirtatious manner. As noted above, HPD typically has a chronic course, although symptom severity may decrease somewhat as the individual ages.

History and Criticisms

The concept of the histrionic personality historically dates back to the Greek concept of "hysteria" (i.e. the wandering uterus), and was long seen as a condition endemic to women. HPD, as a diagnosis, was not included in the DSM until the second edition (DSM-II; APA, 1968) as "hysterical personality disorder." The disorder was later labeled histrionic personality disorder in DSM-III (APA, 1980), which it remains today. Throughout its history, there has been much disagreement regarding the HPD's conceptualization, and the diagnostic criteria have shifted throughout various revisions of the DSM in order to operationalize the disorder as well as discriminate it from other personality disorders. Accordingly, the validity of the HPD construct has historically been scrutinized.

Issues related to the classification and conceptualization of HPD continue to be a topic of debate. HPD is presently classified in Section II of the DSM-V as a "Cluster B" personality disorder (i.e. dramatic, emotional, and erratic cluster), along with borderline personality disorder, narcissistic personality disorder, and antisocial personality disorder. Notably, there is significant overlap between these Cluster B diagnoses, including interpersonal relationship difficulties, self-centeredness, impulsivity, attention-seeking, affective instability. Such overlap complicates the conceptualization, assessment, and diagnosis of these disorders. HPD also shares some features with dependent personality disorder, primarily an excessive need for reassurance and approval. In addition, HPD has been criticized for lacking a scientific base and an adequate and growing empirical literature, and has been included among the personality disorders whose literature is described as "dead" or "dying" (Blashfield et al, 2012). While there has been some recent research on the topic, HPD research greatly lags behind that of other PDs, such as borderline personality disorder.

Furthermore, HPD has been criticized for its potential gender biases. As mentioned above, "histrionic" comes from the term "hysteria" – a term that has been used to discount

women's problems when not easily understood, as well as describe difficult-to-treat female patients (Beck et al., 2004). Additionally, the diagnostic criteria appear to involve maladaptive exaggerations of somewhat stereotypical feminine traits, which contribute to the belief there is gender bias in HPD. Research investigating whether there is a gender bias in the actual diagnosis of HPD is mixed. According to the DSM-V, in clinical settings, HPD is more frequently diagnosed in females. However, "the sex ratio is not significantly different from the sex ratio of females within the respective clinical setting" (p. 668) and studies using structured assessments demonstrate similar prevalence between genders (APA, 2013). Notably, research has suggested that, when presented with identical symptoms, clinicians are more likely to diagnose women with HPD in women and men with antisocial personality disorder (e.g. Samuel & Widiger, 2009).

Assessment and Treatment

Assessment

Currently, there is no widely utilized or accepted HPD-specific assessment (e.g. interview, measure, questionnaire) for diagnosis. There are, however, several assessment interviews and inventories that examine all personality disorders (including HPD) as well as personality traits. Assessment of HPD typically consists of a combination of psychosocial interviews, structured or semi-structured clinical interviews, and self-report inventories. It is important for clinicians to examine each diagnostic criterion, as well as consider aspects such as culture, gender, other diagnoses, and other biopsychosocial factors to determine whether an individual meets full criteria for the diagnosis.

Treatment

Personality disorders, by definition, represent chronic, ingrained patterns of behavior. Therefore, personality disorders are among the most difficult to treat – HPD being no exception. Unfortunately, research assessing HPD interventions is presently lacking. For example, there are currently no randomized controlled trials for the treatment of HPD, nor are there any standardized, evidence-based treatments specifically designed for HPD. However, there are some notable treatment approaches that can be utilized for HPD.

Cognitive behavioral therapy (CBT) is one widely used psychotherapeutic approach that can be utilized to treat HPD. According to CBT theory, thoughts, emotions, and behaviors interact and influence one another. Often, individuals with psychopathology have skewed, unrealistic thought patterns (e.g. nobody likes me, I am not good at anything), which, in turn, affect one's emotions and behaviors (e.g. increased sadness, increased isolation). Accordingly, a goal of CBT is to help an individual change her or his thinking to be more in line with reality. An individual with HPD is conceptualized from a CBT perspective as assuming that they are inadequate and unable to manage life on their own and that in order for life to be worthwhile, they must be loved by everyone all the time. Accordingly, one with HPD will seek attention and approval to ensure that others will meet his or her needs (Beck et al., 2004).

Group therapy has also been suggested as a treatment approach for HPD (Beck et al., 2004). Group therapy allows one to interact with others in the therapeutic environment, and could possibly help those with HPD confront aspects of the disorder that interfere with their daily functioning (e.g. manipulation, attention seeking). Further, the group context could possibly help individuals develop relationship skills. Psychoanalytic therapy is another potential intervention that has been recommended (Oldham, Skodol, & Bender, 2005).

The nature and presentation of an individual with HPD can complicate treatment. For example, HPD patients can be suggestable, which could make one susceptible to agreeing with and following whatever the therapist recommends. Additionally, the superficial, dramatic nature of the patient could make it difficult for a healthy therapeutic relationship to form. HPD patients may also be prone to manipulate as well as push limits and boundaries. Further, their need for attention and approval and affective instability might encourage clinicians to make hasty decisions as well as potentially cross boundaries (Oldham et al., 2005).

Alternative Conceptualizations and Future Directions

When the DSM-V Personality Disorders Workgroup initially released their proposed alternative model of personality disorder diagnosis (DSM-AM), HPD was among the omitted personality disorder diagnoses. The rationale for HPD's deletion as a categorical diagnosis was that there was a lack of empirical studies focusing on HPD. The DSM-AM was not officially adopted at the time of the DSM-V's publication, and is currently described in Section III – Emerging Measures and Models. Notably, a unique aspect of the DSM-AM is that it includes a dimensional trait component – which could be utilized to capture the construct of HPD. In this new system, the HPD construct would be relegated to the dimensional trait model, and an individual with HPD traits could receive the diagnosis "personality disorder – trait specified" rather than a standalone categorical diagnosis. Within this model, HPD is said to be captured as a combination of elevated emotional lability, and the antagonism facets of manipulativeness and attention seeking.

The DSM-AM is not the only dimensional trait model that has been used to conceptualize HPD. A growing body of research has investigated personality disorders, including HPD, from the perspective of the Five Factor Model (FFM) – a well-validated general model of individual differences. The FFM is hierarchical in nature and consists of five broad dimensional domains (neuroticism, extraversion, openness to experience, agreeableness, and conscientiousness), and each domain has six facets. From an FFM perspective, HPD is conceptualized as elevated neuroticism facets (i.e. depression and self-consciousness), extraversion (i.e. gregariousness and excitement seeking), openness (i.e. fantasy and feelings), and the agreeableness facet of trust.

Notably, the future of HPD as a diagnosis is unknown. While HPD has been the focus of some recent research, researchers have described it as a "dying disorder" (Blashfield et al, 2012). Should the current DSM-AM be officially adopted in future revisions of the diagnostic manual, the HPD diagnosis will cease to exist in its current form. However, that does not necessarily mean that the personal, social, and occupational impairment associated with the HPD construct will vanish along with it. Accordingly, further research will

be needed to better understand, assess, and effectively treat those with HPD as well as HPD traits and behaviors.

Dependent Personality Disorder

Robert F. Bornstein

Adelphi University

Mental health professionals have long recognized that certain people have a dependent personality style – a tendency to look to others for nurturance, guidance, protection, and support, even in situations where autonomous functioning is warranted. The descriptions of Dependent Personality Disorder (DPD) in the *Diagnostic and Statistical Manual of Mental Disorders,* fifth edition (DSM-5) and the *International Classification of Diseases,* tenth edition (ICD-10) are consistent with this longstanding conceptualization of the dependent personality: in both diagnostic manuals DPD is defined as a pervasive and excessive need to be cared for that leads to submissive and clinging behavior, and fears of separation. In addition to manifesting this pattern of dysfunctional behavior, to qualify for a DPD diagnosis the person's dependency-related difficulties must have been present since early adolescence, be consistent over time, and cause marked distress and/or impairment in social and occupational functioning.

Although DPD is associated with a number of negative outcomes (e.g. increased risk for depression, vulnerability to stress-based illness, overuse of health and mental health services), researchers agree that pathological dependency is best conceptualized as a continuum ranging from mild to severe, with no sharp and fixed cutoff distinguishing high levels of "normal dependency" from DPD. As a result, during the past several decades clinical researchers have used measures of DPD and measures of interpersonal dependency (sometimes called *trait dependency*) interchangeably, and many of the DSM-5 and ICD-10 DPD symptoms are derived from studies wherein dependency was assessed using self-report scales (e.g. the Interpersonal Dependency Inventory) or performance-based measures (e.g. the Rorschach Oral Dependency Scale) in lieu of diagnostic interviews. Given the broad array of assessment tools used in these studies, and the myriad populations examined (e.g. psychiatric patients, medical patients, college students, community adults), a sizable evidence base has accumulated over the years, with more than 800 published studies of trait dependency and DPD.

The Evolution of Dependency: From Biology to Relatedness

Clinicians' conceptualization of interpersonal dependency and DPD has evolved considerably since Freud's initial writings on "oral fixation" more than a century ago. Empirical support for Freud's classical psychoanalytic model of oral dependency was sparse, and during the 1940s and 1950s object relations models of dependency gained influence. Although these models differed in the details, they shared a common emphasis on internalized mental images of self and significant figures as central to the etiology and dynamics of pathological dependency. Research confirmed that – consistent with the object relations perspective – individuals with DPD perceive themselves as weak and ineffectual, and view other people as comparatively competent and confident. As a result, dependent people are inclined to look to others for help and support rather than confronting challenges on their own.

Object relations models of dependency and DPD helped set the stage for contemporary integrative frameworks, most notably the cognitive-interactionist (C/I) model. The C/I model contends that the etiology of DPD lies in overprotective, authoritarian parenting, which fosters dependency by preventing the child from developing a sense of mastery following successful learning experiences. In addition, parental overprotection and authoritarianism play a key role in the construction of a representation of the self as ineffectual and weak – a "helpless self-concept." This perception of the self as powerless and ineffectual is the linchpin of a dependent personality orientation, and sets in motion a set of psychological processes that eventually result in DPD. A perception of oneself as powerless and ineffectual will, first and foremost, have *motivational* effects: A person with such a self-concept is motivated to seek guidance, support, protection, and nurturance from other people. These motivations, in turn, produce particular patterns of dependent *behavior*: the person who is highly motivated to seek the guidance, protection, and support of others will behave in ways that maximize the probability they will obtain the protection and support they desire. Finally, a representation of the self as powerless and ineffectual has important *affective* consequences (e.g. fear of abandonment, fear of negative evaluation by figures of authority).

Situational Variability in Dependency-Related Responding

The C/I model differs from other theoretical frameworks in recognizing that while the dependent person's "helpless self-concept" remains stable, the dependent individual's behavior may vary considerably from situation to situation, depending on the demands, constraints, and risks of that situation. When behaving in a passive, submissive manner is likely to strengthen ties to potential caregivers, the dependent person will behave passively and submissively. When active, assertive behavior seems likely to strengthen such ties, the dependent person may behave assertively, even aggressively. Thus, although dependent college students typically show high levels of passivity and compliance around peers, when a figure of authority is present they shift to a more active stance, competing with peers for the attention and favor of the authority figure. Dependent psychiatric and medical patients

are highly compliant with therapeutic regimens, but they also make a greater number of health service visits than do nondependent patients with similar diagnostic and demographic profiles. Although dependent men often behave submissively around friends and romantic partners, when they believe that an important relationship is threatened (e.g. that their partner may be about to abandon them), they may become quite aggressive, and on occasion even violent. As a result, high levels of dependency in men are associated with increased risk for perpetration of partner abuse.

In sum, contemporary integrative models of interpersonal dependency and DPD conceptualize dependency-related responding as proactive, goal-driven, and guided by beliefs and expectations regarding the self, other people, and self–other interactions. These models also shift the locus of stability in dependency from surface responding to underlying thought and motive: Although the behaviors of dependent persons vary considerably from situation to situation, the dependent person's core beliefs (a perception of oneself as powerless and ineffectual) and motives (a desire to strengthen relationships with protectors and caregivers) remain constant.

Contextualizing Dependency: Culture and Gender Role

Beyond the importance of beliefs regarding the self and other people, contemporary thinking regarding interpersonal dependency and DPD has increasingly emphasized the influence of culture and gender role in shaping the experience and expression of underlying dependency strivings. Several investigations have shown that sociocentric cultures (i.e. cultures that emphasize interpersonal relatedness over individual achievement) are more tolerant of dependency in adults than are more individualistic cultures (i.e. cultures that emphasize competition and achievement over group harmony). Not surprisingly, adults in India and Japan (cultures that have traditionally been relatively sociocentric) report higher levels of dependency than do adults in Great Britain and America (cultures that are among the most individualistic). As traditionally sociocentric cultures become Westernized and incorporate individualistic values and norms, self-reported dependency levels tend to decrease, and adults in those cultures – especially men – become increasingly conflicted regarding how best to integrate dependency urges with strivings for autonomy and independence.

Gender role socialization helps shape the experience and expression of dependency as well. In most Western societies, dependent behavior is regarded as less acceptable in boys (and men) than in girls (and women); as a result, men tend to be more reluctant than women to express dependency needs openly. By late childhood, significant gender differences in self-reported dependency emerge and remain relatively stable through later adulthood, at which time men's dependency scores increase and the gender gap closes. Meta-analyses confirm that women in early and middle adulthood score higher than men on every questionnaire and interview measure of interpersonal dependency and DPD for which reliable gender difference data are available. Studies also show that women receive DPD diagnoses at significantly higher rates than men do in inpatient and outpatient settings.

Implicit and Self-Attributed Dependency

Interestingly, the patterns of gender differences that emerge consistently when self-report and interview measures are used do not occur when dependency is assessed via performance-based measures. This is because self-report scales such as the Interpersonal Dependency Inventory assess *self-attributed dependency needs* – dependency needs that are recognized and acknowledged by the patient. Performance-based measures such as the Rorschach Oral Dependency Scale assess *implicit dependency strivings* – dependency needs that shape dependent responding indirectly, often with little or no awareness on the patient's part. Gender role socialization appears to influence women's and men's self-attributed dependency, but not their underlying, implicit dependency; in contrast to findings obtained for questionnaire- and interview-assessed dependency and DPD, women and men do not differ in overall level of implicit dependency.

Given the contrasting psychological processes that are involved in responding to self-report and performance-based dependency tests, it is not surprising that scores on these two types of tests tend to be modestly intercorrelated, with *r* typically in the range of .2 to .3. A complete picture of a patient's dependency strivings requires that self-report test data be combined with performance-based test data, and evidence confirms that integrating implicit and self-attributed dependency scores provides better predictive power than reliance on one type of score alone. It is possible – and in fact fairly common – that a patient will score consistently high (or consistently low) on both types of measures, which would indicate a convergence between that patient's implicit and self-attributed dependency needs, and suggest that self-reports are a reasonably accurate reflection of the person's underlying dependency strivings. Alternatively, multimethod assessment sometimes reveals a divergence between implicit and self-attributed dependency. In one situation, a person may have high levels of underlying dependency but either is unaware of this or unwilling to acknowledge it when asked; this person is best described as having a personality style characterized by *unacknowledged dependency*. In the other situation, a person may have low levels of implicit dependency needs but nonetheless chooses to present him- or herself as being highly dependent; this person is best described as having a *dependent self-presentation*. Although people of either gender may be found in both categories, men more than women tend to manifest unacknowledged dependency, and women more than men show a dependent self-presentation.

The Future of Dependency and DPD

Studies continue to explore the impact of interpersonal dependency and DPD in a variety of contexts and settings; two themes have emerged which will shape future research on DPD.

Healthy and Unhealthy Dependency

Recently investigators have distinguished two distinct manifestations of underlying dependency: destructive overdependence (DO) and healthy dependency (HD), the former characterized by impulsive, unmodulated help-seeking and the latter characterized by

more mindful, goal-directed efforts to obtain help and support. Studies involving the Relationship Profile Test, which provides separate indices of these two dependency styles (along with a third dimension, dysfunctional detachment) have shown that DO and HD have different correlates and consequences in college students, community adults, psychiatric inpatients and outpatients, medical patients, and nursing home residents. Adolescents and adults with DO and HD differ with respect to self-concept, attachment style, interpersonal relations, life satisfaction, affect regulation, and defense and coping style. Although psychotherapy for highly dependent patients has traditionally focused on diminishing underlying and expressed dependency, recent therapeutic approaches also attempt to shift unhealthy manifestations of dependency toward healthier expressions of underlying dependency needs.

Emerging Trait Perspectives

When the DSM-5 Personality and Personality Disorders Work Group delineated a trait-based model of personality pathology they proposed that pathological dependency may be usefully conceptualized as reflecting high scores on three dimensions: anxiousness, submissiveness, and separation insecurity. Along somewhat similar lines, the long-standing Five Factor Model conceptualizes DPD as reflecting high levels of separation insecurity, helplessness, unassertiveness, gullibility, and subservience. Both of these trait perspectives provide important information regarding the interpersonal dynamics of dependency and DPD, but because both trait models have relied primarily on self-report evidence to derive and test their frameworks, both frameworks capture the core elements of self-attributed (but not implicit) dependency. In addition, neither model incorporates the well-established finding that the expression of underlying dependency needs varies over time, and across context. The trait patterns that underlie high levels of implicit dependency (or unacknowledged dependency), and those that may help account for situational variations in dependency-related responding have yet to be delineated.

Individual Differences in Acculturation

Martin J. La Roche[1] and Luz M. Garcini[2]

[1]*Boston Children's Hospital/Harvard Medical School*
[2]*Rice University*

Central Characteristics

The concept of *acculturation* has been gaining prominence since the 1900s, particularly in the fields of anthropology, sociology, public health, and psychology. Generally, acculturation is defined as a socio-cultural process in which members of one cultural group change as a result of the continuous contact with individuals of a different cultural group. This initial conceptualization requires that several points be clarified. First, the effects of acculturation are observed at multiple levels, such as the psychological level, which includes alterations in person(s)' language, behaviors, values and customs and at the contextual level, which involves changes at the institutional and socioeconomic level. Second, these changes are the result of the contact between two cultures which are the native culture and host culture. The native or first culture is the culture from which the person(s) immigrated. In contrast, the host culture is the one into which the person(s) has immigrated. Nevertheless, as a result of globalization it is more difficult to distinguish distinct and separate cultures. Third, newer conceptualizations of acculturation are considering the influence of more than two cultures. Finally, there are many means through which people acculturate, from dominance over another's culture through either military or political conquest to social media influence.

Related Terms

Acculturation is often confused with *acculturative stress*, which refers to the psychological, somatic, and social difficulties that may accompany the acculturation processes. Acculturative stress can manifest in cultural shocks, anxiety, depression and/or other forms of mental and physical maladaptation or distress (La Roche, 2013). The term of *enculturation* describes the process of learning the accepted norms and values of the culture

or society where they live. As individuals enculturate, they learn the accepted behaviors that dictate what is acceptable within society. *Transculturation* refers to the merging or converging of different cultures (Mio, Barker-Hackett, & and Dominguez Rodriguez, 2016).

Acculturation Theories

1. **Single-factor**, which most people refer to as the melting pot approaches, were the first acculturation theories to be developed and are often measured through one continuum that underscores the degree to which immigrants adapt or assimilate to a new living environment and adopt the norms, values, and practices of the host society (Mio, Barker-Hackett, & Domenech Rodriguez, 2016). These models had often assumed that immigrants should conform to the host culture to be "successful" or "healthy." Consequently, newcomers were encouraged to assimilate as quickly as possible. "Melting pot" immigration policies were promoted by the United States until the 1970s. Nevertheless, single-factor theories depict the acculturation process as a static, one-dimensional, and linear process. The emergence of two-factor theories was a response to these limitations.

2. **Two-factor**, theories explain the diversity of acculturation behaviors through two orthogonal dimensions. The first dimension is identical to the assimilation factor under-scored by single-factor theories. The second dimension refers to individuals' level of retention or rejection of their native culture or how much they value maintaining their first culture. According to this framework, acculturation strategies can be categorized within four sectors or quadrants. Although individuals employ many and diverse behaviors to cope with their cultural contexts, acculturation strategies are the prevalent types of behaviors or strategies through which individuals negotiate their contact with both cultures (see Berry, Phinney, Sam, Vedder, 2006). These four acculturation strategies are:

    2.1 **Assimilation** strategies involve individuals adopting the cultural norms, attitudes and behaviors of the host culture; while neglecting those of their first culture. Research has found that assimilation can lead individuals to experience symptoms of depression and/or anxiety.

    2.2 **Separation** occurs when individuals reject the host culture in favor of preserving their native culture. Separation is often facilitated by immigration to ethnic enclaves or segregation policies. Research has found that using this strategy can also lead to many mental health problems.

    2.3 **Integration** or the salad bowel approach occurs when individuals can adopt the cultural norms of the host culture while maintaining those of their native culture. Research is finding that more positive health and economic outcomes are related to the use of this acculturation strategy (Berry et al., 2006) and that contact amongst different groups can fuel richer and more complex identities and societies.

    2.4 **Marginalization** occurs when individuals reject both their native and host culture. Marginalization is rare and has consistently been associated with the poorest health indicators, particularly more severe depressive symptoms, and substance use.

Currently, two-factor theories are the prevalent way to conceptualize and measure acculturation. However, most studies suggest that individuals, irrespective of their acculturation strategies, can differ between their private and public life spheres. For

instance, an individual may reject the values and norms of the host culture in private life domains (separation), whereas s/he might adapt to the host culture in the public parts of life (i.e. integration or assimilation), which has led additional models to underscore the possibility of more complex quadrants.

3. **Contextual acculturation** theories underscore the context-specific conditions and behaviors that influence the acculturation process. The context is assessed by ecological conditions, such as the place of residence, the size and form of a family unit, the school system or the cultural features of the cultural enclave.

4. **Developmental acculturation** theories highlight how having contact at distinct developmental periods can result in different acculturation outcomes. Developmental models underscore how acculturation is a dynamic process that needs to measured on several occasions. Unfortunately, much of current acculturation research is still assessed at only one time.

Acculturation Research and Recommendations

The main questions guiding acculturation researchers can be summarized as which aspects of the acculturation process are detrimental and which are protective for specific health outcomes. Research has consistently found that acculturation affects health by impacting lifestyle, levels of stress, access to health resources, and attitudes toward health. Among most immigrant groups, higher levels of assimilation have been associated with negative effects on health behaviors and outcomes, but positive effects on health-care use and access. From a public health perspective, health promotion programs have focused on supporting healthy native cultural behaviors and/or ameliorating the adoption of unhealthy cultural practices of the host country. The effect of acculturation is equally important to assess the effectiveness and acceptability of evidence-based interventions and the evaluation of treatment outcomes contributing to ethnic minorities' health disparities.

The effects of acculturation on physical and mental health are thought to be a major factor in the immigrant paradox or the finding that first generation immigrants tend to have better health outcomes than members of the host culture and that these differences decrease over generations. One prominent explanation for the negative health behaviors and outcomes amongst individuals who are acculturating is that they adopt some of the unhealthy behaviors (e.g. smoking, substance and alcohol use, decreased consumption of "low fat" foods) of the host culture and/or experience much *acculturative stress*. Nevertheless, there is much debate in understanding the immigrant paradox. For example, Garcini, Murray, Zhoe, Klonoff, Myers, and Elder (2016) suggest that first generations' health outcomes are not appropriately measured and that many immigrants, such as those with undocumented immigration legal status, are facing unique, complex, and chronic amounts of distress that are not appropriately measured.

Despite definitions and evidence that acculturation entails a two-way process of change, research and theory have primarily focused on the adjustments and adaptations made by ethnic minorities, immigrants, and refugees in response to their contact with the host culture. Almost one-third of the acculturation research has been conducted with Latinos and a fourth with Asians. Research is needed with different groups such as African and

White Americans. Furthermore, highly influenced by an individualistic paradigm, research has mostly focused on the effects of acculturation on the individual level and neglected how it impacts society.

As the importance of the acculturation process is increasingly recognized, a growing number of theories and measures have been developed. Nevertheless, the growing number of theoretical models and scales makes the acculturation field seem fractured and fragmented, particularly because many scales and theories still lack sufficient evidence. In addition, research that identifies specific mechanisms that operate at different levels of influence is also lacking (Abraido-Lanza, Echeverria, & Florez, 2016). For instance, identifying cognitive mechanisms (e.g. social comparison, cognitive reappraisals, "shift-and-persist" processes) that mediate the association between acculturation and different health outcomes under adverse circumstances and across different subgroups is essential to inform theory, measurement, and intervention development. Likewise, developing a better understanding as to how the immigration experience modifies the composition and dynamics of social networks (e.g. ethnic enclaves) can expand our understanding of the acculturation process and its effects on health and behavior across different populations. Moreover, an interdisciplinary and collaborative approach in examining acculturation is needed that is inclusive of clinicians, researchers, educators, and community partners of diverse backgrounds.

Furthermore, many acculturation scales are too broad and are not generalizable with groups different from those in which they were developed. Also, most measures of acculturation place a heavy emphasis on language preference, proficiency, and use; yet not fully capturing the complexities of language use. This may create significant difficulties in assessing acculturation in groups such of African Americans in which, language differences are not relevant. For acculturation scales to be helpful with specific cultural groups, they must be informed by the characteristics of the group in question and include the specific domain being measured. Abraido-Lanza et al. (2016) recommend that acculturation items be relevant to the issue being studied (e.g. studies of obesity should ask questions about diet). Many of these scales also lack a clear understanding of what culture is or how it differs from ethnicity or race (La Roche 2013). This confusion may lead researchers to misconstrue cultural differences as deficits.

It is important that studies consistently factor out the effects of socioeconomic status on acculturation as means to avoid misattributing the effects of discrimination and low SES to acculturation processes. Covariate control for these should become the norm in all acculturation research, especially research on minority health and well-being (Rudmin, 2008). Furthermore, acculturation has frequently been measured through explicit or conscious scales. However, the impact of culture can be a result of implicit or unconscious influences that are not measured by most acculturation scales. Having neglected implicit cultural influences and effects may diminish the sensitivity of these scales (La Roche, 2013).

Even though the importance of acculturation is such that the history of different civilizations could be partly explained through acculturation patterns, many of its findings are currently questioned or neglected. Some researchers (e.g., Hunt, Schneider, & Comer, 2004) have gone as far as suggesting that cultural and health related research abandon the concept of acculturation. Nevertheless, many findings in the acculturation field have been repeatedly replicated. For example, acculturation research clearly questions the efficacy of immigration policies in which newcomers are solely encouraged to assimilate to the host

culture, as past melting pot immigration policies in the United States did, or erecting walls that only end up marginalizing and alienating immigrants. In contrast, acculturation research indicates that the best path for immigrants is to foster supportive environments in which they are welcomed to develop at their own pace. As a result of this openness, it is more likely that they will not only grow healthier but also become more productive members of society. Health is an outcome of successful acculturation, along with improved income, educational, and social status. One of main challenges researchers face today is to define "success" and "health" in terms that reflect the acculturating person's characteristics and is not defined by researchers' culture.

Allocentrism vs. Idiocentrism

Jeffery Scott Mio

California State Polytechnic University, Pomona

Allocentrism and idiocentrism are terms that relate to individuals and not to societies (Triandis, 1995). Allocentrism are those personality traits associated with collectivistic cultures, and idiocentrism are those personality traits associated with individualistic cultures. However, it is common for people to use the cultural or societal terms – collectivism and individualism – for references to individuals. Thus, one may hear people referring to other people as collectivistic or individualistic as opposed to allocentric or idiocentric.

By far and away, the individual conducting the most work on the distinction between allocentrism and idiocentrism as opposed to collectivism and individualism has been Triandis and his associates (Hui & Triandis, 1986; Hui, Triandis, & Yee, 1991; Triandis, 1995, 2000; Triandis et al., 1986; Triandis, Bontempo, Villareal, Asai, & Lucca, 1988; Triandis, Chan, Bhawuk, Iwao, & Sinha, 1995; Triandis, Leung, Villareal, & Clack, 1985; Triandis, McCusker, & Hui; 1990). Most of these studies have developed measures of allocentrism and idiocentrism or merely defined these terms and underscored their distinction from the cultural/societal equivalents of the terms. For example, in the Triandis et al. (1995) study, the authors examined different ways of measuring allocentrism and idiocentrism and concluded that these constructs were complex and required differing ways of measuring them. Triandis et al. (1986) and Triandis et al. (1988) warned of emic differences between collectivistic and individualistic cultures. For example, when studying the term *self-reliant*, Triandis and his associates found that indiocentric individuals in individualistic societies interpreted the term to involve being independent, whereas allocentric individuals in collectivistic societies interpreted the term to involve not wanting to burden others.

Triandis and his associates' seminal work on the measurement of collectivism and individualism (and their associated terms of allocentrism and idiocentrism) has served as the basis for predictions in other areas. For example, Matsumoto and Kupperbusch (2001) applied the dimensions of allocentrism and idiocentrism to emotional expression. They attempted to replicate Eckman's classic studies comparing Japanese and American research participants on exposure to gruesome images (Eckman, 1972; Eckman & Friesen, 1969,

1971, 1986). In those studies, while both Japanese and American participants displayed horrified expressions on their faces when watching gruesome images (e.g. an amputation of a person's limb, a horror movie segment) when watching the film segments alone, the Japanese participants smiled when viewing these images when the researcher was in the room with them. The American participants still had expressions of horror even with the presence of the researcher. The standard interpretation of this study was that the Japanese participants did not want to show displeasure to the researcher, as such a display would be an implicit criticism of the researcher – someone seen as an authority figure or a superior to the participants. When Matsumoto and Kupperbusch replicated this study dividing American participants (all of European descent) into allocentric or idiocetric individuals, they replicated Eckman's findings, although these results were attenuated from the cross-cultural comparisons. Still, to the extent that the participants were of European descent and living in an individualistic society, Matsumoto and Kupperbusch pointed out the usefulness of categorizing these participants into allocentric and idiocentric individuals purely on the basis of the Hui and Triandis (1986) instrument.

While the Eckman studies on emotional expression explicitly compared participants from a collectivistic culture with those from an individualistic culture, and the Matsumoto and Kupperbusch (2001) study examined European descent participants categorized as allocentric or idiocentric, Dabul, Bernal, and Knight (1995) compared European descent (Anglo, in their term) individuals with Mexican descent individuals in the United States. Dabul et al. examined junior high school children (7th, 8th, and 9th grade students) on allocentrism and idiocentrism. They found that about half of their Mexican descent children's responses to questions about themselves and school-related topics could be categorized as allocentric and about half of their responses could be categorized as idiocentric; most of their Anglo participants' responses were scored in the idocentric direction. Moreover, the Mexican descent participants felt approximately the same about allocentric and idiocentric self-descriptors, whereas the Anglo participants felt that indiocentric self-descriptors were much more important to them than allocentric self-descriptors.

Dutta-Bergman and Wells (2002) examined the comparative happiness of those who were allocentric versus those who were idiocentric in the United States, an individualistic society. They found that those who were idiocentric were happier overall than those who were allocentric. They interpreted their results as allocentrics being somewhat dissatisfied with their lives because they spend so much of their time trying to make others happy and not attending to their own needs. However, while they had nearly 4,000 respondents to a national survey, they did not report the gender participation nor differentiation in allocentric or idiocentric scores. Moreover, they did not know of another study that examined the relative happiness or life satisfaction of allocentrics and idiocentrics in a collectivistic society.

Not surprisingly, there is evidence that allocentric and idiocentric mismatch with cultural values has led to higher levels of distress. Caldwell-Harris and Ayçiçegi (2006) found that allocentric individuals in the United States (an individualistic society) had positive correlations with depression, social anxiety, obsessive-compulsive disorder, and dependent personality, whereas idiocentric individuals had negative correlations with these same disorders. On the other hand, idiocentric individuals in Turkey (a collectivistic society) had positive correlations with paranoid, schizoid, narcissistic, borderline, and antisocial disorders, with allocentric individuals having negative correlations with these disorders.

Zhang, Norvilitis, and Ingersoll (2007) found that idiocentrism was associated with suicidal ideation in both collectivistic (China) and individualistic (United States) societies for women, although allocentrism was seen as a protective factor, which positively correlated with social support, particularly in a collectivistic society.

Monolingualism, Bilingualism, Multilingualism

Antonio E. Puente, Hana Kuwabara, and Andrea Mejia

University of North Carolina Wilmington

Defining Monolingualism, Bilingualism and Multilingualism

Simply stated, *monolingual* describes an individual who has acquired one language, but to define *bilingual* and *multilingual* represents a difficult task. The term *bilingual* primarily describes an individual with possession of two languages, and *multilingual* broadly refers to an individual with two or more languages. However, these rudimentary descriptions alone are not sufficient to appreciate the linguistic abilities of an individual. For example, calling an individual *multilingual* does not provide information regarding the understanding of their various possessed languages, nor does it entail which language is dominant. Dependent on the quantity of possessed languages, an individual can nevertheless be labeled "bilingual" or "multilingual" regardless of specifics encompassing language usage or proficiency.

The consequences of not formally appreciating an individual's linguistic mechanisms compromise psychological complications in social, cognitive, and developmental domains. Imagine a toddler raised by Chinese- and Spanish-speaking parents, with English exposure limited to schooling. The educational system may begin to speculate social or developmental impairments if the child fails to engage with peers or is not meeting expected educational milestones. To deem the observations as true deficits, the toddler's capabilities must be addressed in Chinese, Spanish, and English to rule out impairments attributed to limited English exposure.

The risk of misinterpreting or mislabeling multilinguals is highly probable if their observed impairments are not sought to be understood using sociolinguistic considerations. Unique characteristics and potential varying language abilities must be fully explored to not only understand individual differences that coexist when addressing falsely perceived homogenous groups but also avoid Type 1 errors and other negative consequences.

Linguistic Classifications in Multilingualism

A seemingly homogenous group comprised of individuals who speak the same language still exhibit a high prevalence of linguistic differences. These linguistic differences include, but are not limited to, the extent of an individual's fluency and proficiency, the context or situation the language(s) are used in, the age at which an individual acquired the language, as well as how the language(s) were acquired. These interconnected variables demonstrate clear individual differences that can be measured, while also shedding light on unmeasurable considerations.

Fluency

An individual obtains multiple degrees of classification in terms of fluency due to the combination of understanding, speaking, reading, and writing in one or more languages.

As a result, there are many variations of fluency within and across individuals and the multiple languages they possess. For example, *receptive bilingualism* represents an individual who is able to understand two languages (spoken or written) but is only able to express one. An individual who is a *productive bilingual* not only understands, but can also speak and possibly write in two or more languages.

Proficiency

Sharing similarities with fluency, there are varying levels of proficiency across multilingual individuals that include grammatical knowledge and skills, aspects of communication (fluency; i.e. learning, reading writing, oral communication, numeracy), cross-language interactions, and competence in sociolinguistic discourse. When establishing language proficiency across a range of contexts, the terms "balanced" (equal competence) and "nonbalanced" multilingual denotes the degrees of skill that may be unique across an individual's possessed languages. Other classification methods of proficiency levels concern the underlying mechanism of language mastery and production. Specifically, the mastery of two languages can be categorized by *coordinate bilingualism*, *compound bilingualism*, and *subordinate bilingualism* (Weinreich, 1953). Depicted by linguistic elements being related to their own unique concepts, *coordinate bilingualism* contrasts *compound bilingualism* in that the latter involves having two separate linguistic elements for a single concept. *Subordinate bilingualism* is characterized by the linguistic elements of one of the individual's languages being available only through elements of the individual's other language. While these specific mechanisms are difficult to measure, it is important in recognizing the process of language functioning and the language in which an individual identifies with and perceives the world.

Time of Acquisition

Time of acquisition of the second (or third, etc.) language can be divided into simultaneous, early, and late. *Simultaneous multilingualism* entails the acquisition of two or more languages at the same time. An example of a simultaneous bilingual would be an infant

who is equally exposed to two languages from birth. *Early multilingualism* is characterized by the acquisition of a second language before complete acquisition of the first language, while *late multilingualism* involves the acquisition of an additional language after complete acquisition of a preceding language.

Context

An individual's preferred and best-spoken language is referred as the *dominant language.* However, this ambiguous classification can adapt based on context and across different periods of time. Specifically, a *dominant language* can differ based on the person addressed (e.g. members of family, friends, strangers), the topic of the conversation, as well as the setting or purpose of the encounter. It can also vary across time when describing an individual who may exhibit *subtractive bilingualism,* which is when the competence of the first language gradually declines due to the addition of a second language.

Other Considerations

Language of schooling, formal versus natural language attainment, and the discrepancy between language(s) and culture(s) are other variables that add to the complexity of multilingual individuals. Specifically, the discrepancy between language and culture refers to the false assumption that monolinguals and multilinguals form a homogenous group, respectively. However, there is variability among individuals that share the same language(s) depending on country of origin and subcultural groups. These variances are demonstrated through specific language use, dialect, and cultural emphases on self-expression. There is also variability among the acculturation of the individual and the interaction between their own native culture (and language) and the acquired culture (and language). As a result, individuals who speak the same language(s) cannot be automatically and identically compared, assessed, or evaluated without weighing linguistic considerations.

Bilingualism and Multilingualism in Practical Applications

Research has demonstrated that individuals who vary across linguistic variables differ across social, psychological, and cognitive functions. As a result, it is important to acknowledge an individual's composition of linguistic ability, especially in the context of multiple settings (Salinas, Bordes-Edgar, & Puente, 2015; AERA, APA, & NCME, 2014). Although casual, everyday encounters (e.g. home, work, social) have a greater probability of being marred by discrepancies attributed to language, psychologists have discovered means to limit the negative effect the meta-construct may have on evaluations.

Assessment

To account for the degree of variability across language proficiency and fluency, the language used during an evaluation must be selected within the context of the appropriate setting. For example, when assessing for a possible language disorder, the evaluation should

take place in each language the examinee is familiar with, noting if similar difficulties are observed across each language. In certain situations (e.g. neuropsychological examination), an individual may be evaluated using the language they prefer. To verify language preference and proficiency obtained in conversation or through self-report, objective measures that assess letter fluency, naming, and reading comprehension should also be used (Thames, Karimian, & Steiner, 2016). In addition, data regarding language acquisition, context of the language, and the language used during their formal education attainment should be gathered (Salinas et al., 2015; Rosselli et al., 2013). Together, these variables will produce a clearer depiction of the individual's functioning with limited inference from linguistic variables.

Although multiple constructs of language have been identified as being necessary during the assessment of overt behaviors and functioning, it is important to recognize that they also impact the manner in which emotions, situations, and concepts are interpreted and experienced. For example, Latin cultures have been recognized for placing greater emphasis on the expression of emotions compared to Anglo-Saxon countries (Bhugra & McKenzie, 2010), while those who speak English and German are noted to be more oriented toward technical issues (Puente et al., 2013). Thus, the language(s) used during evaluations that encompass other domains of nonverbal functioning, can produce skewed results if the proper language(s) are not considered.

Clinical Implications

Historically, it was believed that the effect of linguistic abilities when comparing individuals of diverse compositions could be reduced if verbal abilities were not incorporated. However, research has demonstrated the detrimental effects of assuming nonverbal abilities as comparable across individuals who speak different languages and with individuals who have different levels of language proficiency. Not only are there observable language differences when evaluating individuals through a psychological perspective, there are also potential cognitive differences. While investigating the effect of language acquisition and cognitive abilities, research has demonstrated that speaking two languages negatively impacts the performance on some cognitive measures, with an inverse effect as bilinguals age and mature (Puente et al., 2013). These complexities and underlying functioning abilities arise when culture, language, and other variables, not limited to cognition, intertwine. Thus, it is important to practice nonbiased assessment to lessen the potential discrepancies that a misunderstanding of linguistics can bear.

Ethical Concerns

In settings where any form of assessment is involved (e.g. psychoeducational) different avenues can be pursued to ensure a fair and accurate evaluation. For instance, the evaluator should share the same native language as the individual being evaluated in order to establish cultural compatibility and to maintain fluid conversations between both parties (Thames et al., 2016). However, with that not always being a possibility, other means of decreasing the potential discrepancies should be practiced. Using appropriate measures that encompass the accurate language of administration, considering the language the

tests were originally developed, as well as available normative comparison data are all imperative to conduct an ethical evaluation. Without taking these precautions, the entire evaluation can unintentionally produce distorted results.

When linguistic variables that involve the evaluator and examinee are compromised or adapted, the sensitivity and validity of the results must be reviewed with caution. If a modification occurs (e.g. using an interpreter, eliminating test items or subtests, accepting responses in multiple languages), the evaluation may no longer contain conceptual or construct equivalence due to changes that affect the original and intended construct measured (AERA, APA, & NCME, 2014). Consequently, the results are not comparable with normative data and the assessment cannot be accurately interpreted. Although modifications impact the reliability and validity of the assessment, nonstandardized evaluations that accommodate to linguistic and cultural differences have the ability to provide insight that would otherwise be unattainable with standardized constraints (Olvera & Gómez-Cerrillo, 2014). In cases that are unequivocally affected by linguistic abilities, a flexible approach can be used in order to determine what the individual's needs are and to assess the situation or context presented.

Monocultural versus Multicultural

Lori A. Barker and Crystal Ukpong

California State Polytechnic University

Origins of Terms

While a definite origin of the term *monoculturalism* was not found, *multiculturalism* was coined in 1970s Quebec to describe honoring cultural differences while preserving and honoring the traditions of different cultural communities (Hong et al., 2016, p. 51).

Monocultural

Monocultural is defined as "a single, homogenous culture without diversity or dissension" (thefreedictionary.com). As a political ideology, it is where a single social or ethnic group seeks to dominate society through suppression or oppression of other groups (oxforddictionaries.com). It can describe a population with respect to several factors such as race, sexual orientation, age, and class, and each of these factors can be considered as the more dominant factor in comparison to marginalized groups within the same population (e.g. people of color, homosexual, elderly, lower-class) (Batts, 1990). Monoculturalism, as discussed across various disciplines, has been used in reference to population statistics, ideology, the practices of social institutions, as well as the advantages and disadvantages afforded members of different groups which result from it.

In the psychological literature, the topic is more specifically discussed as *ethnocentric monoculturalism*. Taylor (2006) defines ethnocentric monoculturalism as the belief that one's own culture is normal and valid and that other cultures are abnormal, inferior, or pathological. Such beliefs then justify the differential treatment of individuals from other groups. Whichever group in society holds the majority social power defines the norm. In the United States, European American culture is the dominant group; therefore, they define the dominant cultural values that are considered the norm; all other cultures are considered abnormal, and pressure is placed on those deviant groups to conform.

Sue (2004) delineates five attributes of ethnocentric monoculturalism: (1) belief in the cultural superiority of one's own group, and sense of entitlement; (2) belief in the inferiority of other groups; (3) the power to define reality or to impose one group's beliefs on another; (4) manifestations in institutions through biased structures, programs, policies, and practices; and (5) the invisible veil of "personal and institutional injustice that operates outside the level of conscious awareness" (p. 766), including the American cultural myths of meritocracy, equal opportunity, and fair treatment.

Several authors assert that the field of psychology has a history of ethnocentric monoculturalism (e.g. Riggs, 2004; Sue, 2004; Sue, Bingham, Porché-Burke, & Vasquez, 1999; Taylor, 2006). Sue et al. (1999) comment on how the concepts and theories of psychology were created in and taken from a Eurocentric context and may not be applicable to culturally diverse populations. Historically, psychology has espoused mainstream Western culture as the norm and variations away from this as deviant. At times, psychology has actually supplied ammunition in the form of research and theory that has supported themes of racial inferiority, misogyny, and homophobia (Hall, 2014).

For example, Riggs (2004) argues that current conceptualizations of mental health and mental illness are based on a Western, Eurocentric standard, and anyone who does not fit that model is considered mentally ill. The current models do not account for other cultures who may attribute mental illness to sources beyond the individual, such as the environment, the collective, or the spiritual realm. In other words, assumptions regarding a universal definition of mental health pathologize individuals from diverse cultural groups and ultimately result in their oppression.

Multicultural

Multicultural is defined as pertaining to, or relating to many different cultures or ethnic groups (Dictionary.com). *Multiculturalism* is defined as "the presence of, or support for the presence of, several distinct cultural or ethnic groups within a society" (Dictonary.com). It is the belief that various cultural groups can coexist in a society where each merits equal value and opportunity. As a philosophy, multiculturalism has influenced a wide range of disciplines, including education (e.g. Banks & Banks, 2004), political science (e.g. Parekh, 2000), medicine (e.g. Wear, 2003), as well as psychology.

The basic assumptions of multiculturalism are tolerance, respect, inclusion, sensitivity, and equity (Mio, Barker, & Domenech Rodriguez, 2016). *Tolerance* refers to a fair, open, and objective attitude toward people and ideas that differ from your own. *Respect* means to show regard or consideration for differences. Inclusion involves active efforts to reverse the historical exclusion of certain groups in society. *Sensitivity* is the acknowledgment that cultural differences exist and consideration of these differences in one's interactions. *Equity* refers to equal access to opportunities and resources, including provision of extra assistance to those who have historically not had equal access.

As an action-oriented approach, multiculturalism also includes the concepts of empowerment, social justice, and social change (Banks, 2010; Gorski, 2010). In other words, it is not enough to simply talk about differences; we must actively work to eliminate prejudice, discrimination, and oppression. *Empowerment* means helping marginalized, disenfranchised, and mistreated groups stand up for their rights and fight for equal treatment. *Social*

justice means working toward equity, where every citizen has equal access to the rights, privileges, opportunities, and resources available within society. Achieving these goals requires widespread *social change*. This means implementing policies and practices to ensure everyone receives fair treatment and creating a social environment in which differences are valued and respected. In other words, multiculturalism is more than a philosophy; it is a "social intellectual, and moral movement" (Fowers & Davidov, 2006, p. 581) (Mio, Barker, & Domenech Rodriguez, 2016).

Multiculturalism as a philosophy has been very influential in the field of psychology (Fowers & Davidov, 2006; Hall, 2014; Sue, Bingham, Porché-Burke, & Vasquez, 1999). Multiculturalism within psychology means infusion of the basic tenets into all activities of the profession, including research, teaching, clinical work, and consultation. The path toward multiculturalism in psychology has not been a smooth one. As mentioned above, the field has been guilty of monoculturalism. However, the hard work of many pioneers pushed the profession to adopt a multicultural perspective. The American Psychological Association (APA) officially acknowledged the importance of a multiculturalism within the field through its adoption of the Multicultural Guidelines (2003, 2017). The APA (2008) report on the implementation of the original Guidelines states:

> As psychologists, we recognize the ever-increasing racial, ethnic, and cultural diversity of America and the need to incorporate respectful understanding of group differences in our professional practice, research, and teaching. As an organization, APA recognizes the critical need to attend to diversity in our own house and make certain that our policies and publications appropriately reflect affirmative steps toward inclusive thought and action. (p. v)

The importance of multiculturalism is also recognized in the APA Ethics Code, which states that psychologists should be aware of and respect cultural, individual, and role difference, consider these factors when working with individuals from diverse groups, and work to eliminate the effects of bias and prejudice in their work (APA, 2017).

The field moved away from the term *ethnic minority psychology* to *multicultural psychology* sometime during the 1990s (Hall, 2014). This took place because, when contrasted with the term *minority*, the term *multicultural* is considered more inclusive because it goes beyond race, ethnicity, and country of origin to include other historically marginalized identities such as gender, sexual orientation, socioeconomic status, religion, etc. It is considered more accurate because globally, people of color constitute a numerical majority, and by the year 2044 census projections predict the United States will be "majority minority" (US Census Bureau, 2015). It is more empowering, because it no longer implies that one group is of lesser status than another.

The infusion of multiculturalism within psychology is not without controversy. Riggs (2004) suggests that multiculturalism actually works to continue the monoculturalism of mainstream White psychology, because when White culture is described as "one of many cultures," it may fail to shed light on the oppressiveness of White culture. Franklin (2009), Jose (2015), and Sue et al. (2009) express concern that the move toward inclusion, a broad agenda, and development of common goals and interests between groups may drain resources and take the focus away from the targeted interests and

needs of specific ethnic groups. In addition, important topics (e.g. racism, sexism, and homophobia) within multiculturalism may be overlooked, and individuals exempted from confronting their own prejudices.

Conclusion

Despite some of the potential problems with multiculturalism, most emphasize the importance of a multicultural perspective within the field of psychology, as summarized in the following quote from Sue (2004):

> There is a great need to develop a truly multicultural psychology that recognizes important dimensions of the human condition such as race, culture, ethnicity, gender, religion, sexual orientation, and other sociodemographic variables. A psychology that does not recognize and practice diversity is a psychology that is truly bankrupt in understanding the totality of the human condition. It will forever perpetuate a false reality that provides advantages for certain groups while disadvantaging and oppressing others. As long as the invisible is not visible, the profession of psychology may continue to operate from monocultural theories and practices that deny the rights and privileges due to all individuals and groups. Biculturalism

Y. Evie Garcia

Northern Arizona University

Introduction and Definition

Biculturalism describes one's status of being identified with two cultures, internalizing, or containing within oneself, the identity and/or behaviors of both cultures. Biculturalism encompasses a variety of situations in which the individual is part of two systems of values, customs, behaviors, and/or languages. Generally, the term refers to being a member of two ethnic cultures, a culture of origin or heritage and a second culture which often functions as the more dominant culture. Less commonly, biculturalism is also applied broadly to subcultures of identity that may include religion, sexual orientation, gender identity, geographic location, profession, and social group. For example, women working in traditionally male professions may be said to be operating both in a female culture and a male (dominant) culture, each of which has distinct belief systems, values, and behaviors. Biculturalism occurs as a result of a variety of situations, including immigration, interethnic relationships, mixed heritage, colonialism and war-related occupations, expatriation, and international educational opportunities.

The essence of being bicultural merely implies the presence of two cultures but does not indicate a degree to which the separate cultures are integrated or the degree of fluency achieved in each culture. For example, one can be bicultural by immersing in one culture while rarely interacting with the other. Biculturalism therefore implies that one has an option to primarily dwell in either or both cultural realms.

Theories of Biculturalism

Theories of bicultural adjustment vary with more recent perceptions couching biculturalism within the broader concept of acculturation. Acculturation is described as the process of adapting to a new culture without giving up aspects of the original, inherited culture.

Biculturalism was initially viewed on a unidirectional continuum that ranged from *separation* (adherence to the original culture) to *assimilation* (fully adopting only the new culture) with biculturalism (equal incorporation of both cultures) and marginalization (equal rejection of both cultural identities) both in the middle of the continuum and hard to capture as separate concepts. This was unfortunate since biculturalism has been shown to lead to more emotionally healthy outcomes, such as greater life satisfaction, stronger self-esteem, and positive affect. In addition, biculturalism is also related to markers of socio-cultural success, including higher academic, career, and social achievement. Marginalization has been shown to lead to the least emotionally and socially healthy outcomes.

More recently, biculturalism has been recognized as a bi- or even multidirectional concept that takes into account the degree of identity and involvement with each culture, rather than weighing the cultures against one another on a continuum that implies a zero-sum approach where greater involvement in one culture implies less involvement with the other. Affiliation and loyalty to each culture is viewed on a number of dimensions, including language, social group, daily behavioral routines, cultural traditions, values, knowledge and beliefs, communication patterns, level of cultural identity, and societal or systemic aspects such as perceived discrimination, immigration status, and family structure and socialization.

Biculturalism is associated with higher levels of cognitive complexity and better performance on tasks requiring creativity. From a cognitive theory perspective, integration of disparate aspects of two different cultures is thought to activate separate cognitive schemas (frameworks for organizing information). Biculturals' attempts to connect disparate schemas and to find similarities between them may lead to increased cognitive complexity and creativity. Flexible shifting or alternating between the two cultural frameworks is called *cultural frame switching*.

In terms of individual differences and biculturalism, Phinney and Devich-Navarro's (1997) work with African American and Mexican American youth identified three bicultural types: *blended*, *alternating*, and *separated*. Bicultural individuals in the same family may engage differently with their bicultural statuses. One member may blend both cultures, expressing a stable identity as bicultural. A second member may be equally competent in both cultures but may view the two cultures as more disparate, choosing to alternate between cultures, the situation, or environment determining identity. These individuals might dress and feel more Western at work but may wear traditional ethnic clothing and feel more ethnic at home. Still a third member of the family may primarily identify with the culture of heritage and view the self as separate from the more dominant Western culture.

Roccas and Brewer (2002) suggested four categories of what they call social identity complexity: *merger*, *compartmentalization*, *dominance, and intersection*. The first three types are roughly consistent with Phinney and Devich-Navarro's (1997) blended, alternating, and separated bicultural types. Roccas and Brewer (2002) added a unique fourth intersection type of bicultural who lives at the junction of identities, virtually creating a third culture out of biculturalism itself, identifying mainly with other bicultural peers.

Building on earlier theory that addressed individual differences in terms of types of bicultural individuals, Benet-Martínez and colleagues (for a comprehensive review see

Cheng, Lee, Benet-Martínez, & Huynh, 2014) identified the subjectively perceived relationship between one's two cultures as key to understanding individual differences in bicultural identity. Bicultural identity integration refers to the degree to which both cultural identities are blended and harmonious within the self. Higher levels of bicultural integration require bicultural competence, which includes internalization of both cultures' basic beliefs and values, positive attitudes toward both cultural groups, bicultural efficacy (confidence in ability function effectively in two cultures with a stable sense of identity), verbal and nonverbal communication skills in both cultures, role repertoire (culturally appropriate use of interpersonal skills), and groundedness (stable social networks in both cultures; Laframboise, Coleman, & Gerton, 1993).

Competence in both cultures, perceived *harmony versus conflict,* and *cultural blendedness versus compartmentalization* are key determinants in bicultural identity integration. Accurate recognition of each culture's social cues contributes to effective behavioral responses. Degree of success in these efforts serves to reinforce increased or decreased integration of the two cultural identities.

Development of Bicultural Identities

Differences in development of biculturalism have been associated with generational status (e.g. age of immigration vs. first generation). Tsai, Ying, and Lee (2000) found that for Chinese Americans who immigrated prior to 12 years of age, engagement in American culture was negatively associated with identification with Chinese identity. Conversely, for Chinese Americans who immigrated to the United States after 12 years of age, engagement with Chinese culture was negatively associated with American identity. First generation Chinese Americans born in the United States had no correlations between involvement and identity with either culture.

Facility in language of each culture (i.e. bilingualism) impacts bicultural competence in terms of effective social engagement. Personal volition regarding immigration circumstances (voluntary vs. forced immigration) is also associated with higher levels of bicultural integration. Personality factors, such as low neuroticism, influence willingness to engage in new cultural experiences. Previous positive or negative bicultural experience correlate with higher or lower bicultural identity integration, respectively. In addition, environmental context, including acculturative stress, intercultural conflict, discrimination, and cultural isolation contribute to individual differences in bicultural identity development.

Measurement

Many studies of biculturalism employ typical measures of acculturation used in monocultural studies. One measure specifically designed to address biculturalism is the *Bicultural Stressors Scale* (Romero & Roberts, 2003), a 14-item, Likert-type scale that measures aspects of biculturalism: intergenerational conflict, discrimination, language stressors, and peer pressure to conform with cultural heritage. A second approach includes versions of the

Bicultural Identity Integration Scale (BIIS-1; Benet-Martínez & Haritatos, 2005), a 14- or 19-item (depending on the version), Likert-type measure now with two scales, blendedness and harmony, that evaluate the strength of bicultural identity integration (Cheng, Lee, Benet-Martínez, & Huynh, 2014).

Limitations and Future Directions

The bulk of research on biculturalism has been done with Asian American participants and implications for generalizability are unclear. Research in other countries and with other US populations, particularly Latinos and African Americans, is increasing and will likely illuminate culture-specific applicability of work done thus far. Further research is needed regarding individual differences that influence development and integration of bicultural identity, such as personality factors and interethnic heritage versus acquired biculturalism.

Biracial and Multiracial Individuals

Jude Bergkamp, Katja Ermann, and Vanessa Geissler

Antioch University Seattle

Introduction

In 2008, the United States elected the first biracial president. From eugenic roots to federal rulings and US Census categorization, biracial identity has been intrinsically linked to the racial dynamics of our country. The field of psychology reflects these dynamics, moving from a place of pathology to one of racial integration. Yet, research on this topic is still in its infancy.

Historical Context

In the early United States, there was both the reality of interracial mixing and the legal prohibition of it as soon as Europeans arrived. Innately racist social policies of segregation aimed to prevent the spread of perceived undesirable traits by criminalizing sex, cohabitation, and marriage between a White individual and an individual of color. The concept of miscegenation, or sexual relations between individuals of different races resulting in procreation, came from the eugenic movement in Europe in the early twentieth century, a set of beliefs and practices that aimed to encourage the reproduction of individuals with perceived desired traits.

The child of interracial mixing was marginalized and disenfranchised, seen as tainting racial purity and threatening social and political systems that dictate power and privilege. Using the construct of hypodescent, the automatic external assignment of the perceived inferior race to the child of miscegenation, individuals with any amount of African ancestry were classified as Black; this idea was known as the "one-drop" rule, and gradually codified into law throughout the twentieth century. Terms like quadroon, octoroon, and quintroon were used to designate the proportionality of hypodescent, with the assumption that once there was racial impurity, it would persist as legacy. While there were proportional variations across

states and differences regarding Native Americans and African Americans, the underlying principle of European superiority and eugenics persisted.

In 1967, state anti-miscegenation laws barring marriage between Whites and Blacks were repealed in the *Loving v. Virginia*, 388 U.S. 1 ruling (Loving, 1967). The court ruled this law held no legitimate purpose, and was instead hateful and distasteful towards US citizens, and violated the Due Process Clause of the Fourteenth Amendment. Subsequently, the United States saw an increase in interracial marriages that spawned a large number of multiracial births. From 1970 to the early 1990s the number of interracial marriages increased from 310,000 to 1.4 million, and in 2008 there was an estimated 2.6 million (Rockquemore & Brunsma, 2008). The resulting "biracial baby boom" has grown from an estimated 1% of the population in the 1970s to 5% in 2000 and is expected to rise exponentially (Masuoka, 2008).

The 2000 US Census was the first to allow respondents to self-identify as multiracial for official government counts, rather than "other," a catch-all category conveying little to no meaning (DaCosta, 2007; Nagai, 2010). In 1993, multiracial representatives suggested to lawmakers that adding either a "multiracial" option, or allowing for the selection of all applicable racial categories would offer better recognition of this growing population (DaCosta, 2007). The 2010 Census reports approximately 9 million (2.9%) multiracial persons reside in the United States, a 32% increase from 2000 (United States, 2012). Of the 9 million residents, 92% of multiracial respondents checked just two races. The most common multiple race combinations identified were: Black and White (1.8 million), White and some other race (1.7 million), White and Asian (1.6 million), White and American Indian and Alaska Native (1.4 million).

Biracial and Multiracial Identity Development Models

E. Stonequist (1937) was the first scholar to address biracial identity development, and numerous racial identity theories have existed thereafter in an attempt to conceptualize multiracial identity development. Singular racial identity development (RID) models do not account for the processes that mixed-race individuals experience (Rockquemore, Brusma, & Delgado, 2009). Further identity development models were developed by Poston (1990), Root (1990), Kerwin and Ponterotto (1995), and Rockquemore (1999).

The first prominent academic theory to address the identity formation of biracial individuals was popularized by Everett Stonequist's 1937 book titled *The Marginal Man: A Study in Personality and Culture Conflict*. He asserts that the biracial nature of the individual creates a need to reconcile two distinct and antagonistic cultures. The marginal man will usually attempt to identify with the dominant culture, but may find ways to serve as a leader to the disempowered culture. The biracial identity is devoid of the co-constructed clarity of "we" versus "they," which manifests in isolation, alienation, and stigmatization. Owing to the individual's anomalous position in society, he or she will become the target for hostile sentiments from both parent races toward one another, and this will inevitably cause maladjustment in the individual.

Stonequist suggested a three-phase life-cycle for biracial individuals. As a child, the biracial individual is introduced to parent cultures but is not aware of the differences in power or privilege, and usually identifies with the dominant race. In the crisis phase, the

individual experiences a crisis of identity and belonging characterized by rejection, dissonance, and ambiguity. This results in a maladjusted divided identity, applying the negative attitudes of parent cultures to him or herself. In response, the individual may continue to identify with the dominant culture by attempting to pass, identify with the subordinate group, or attempt to extricate from any racial identity. Stonequist emphasized the potential for biracial individuals, due to their distinctive understanding of both parent cultures, to be a cultural liaison between the two and a spokesperson for the subordinate group. Stonequist's theory is considered the precursor to future identity development models, but has been critiqued for blaming the individual or miscegenation itself for identity problems, instead of placing between-group prejudice as the core of the problem.

W. C. Poston (1990) asserted that previous monoracial models of RID were difficult to apply to biracial individuals due to inherent limitations: the insistence that biracial individuals need to choose one primary identification; would initially reject their minority identity at an earlier stage and reject the dominant culture at a latter stage without allowing for integration of multiple identities; and may not experience acceptance into either parent culture, whether minority or dominant. Poston's model starts with *personal identity* in which the young person is generally unaware of racial and ethnic differences. At the *choice of group orientation* stage the person is pressured by family, peers, or social groups to choose a singular identity and could result in crisis and isolation. The person's previous experience of prejudice and rejection can influence this choice. The *enmeshment/denial* stage involves a loyalty-pull in which the individual chooses one parent culture over another and experiences confusion and guilt in the process. The fourth stage of *appreciation* for both parent cultures is needed to progress. The final stage of *integration* is where the individual establishes a secure, valued, and coherent racial identity.

Root (1990) identified four processes for biracial individuals. In the *acceptance of the identity society assigns* stage the biracial person will adopt the racial group that they have been socialized to identify as by others. In the *identification of both racial groups*, the individual will positively self-identify as biracial. In the *identification of a single racial group* stage, the individual consciously decides to identify as a single race regardless of their biracial makeup, how their siblings self-identify, or what society imposes on them. This status is not considered problematic for the individual; however, it is important to note that identifying with a single racial group may not be acceptable to others when the biracial individual's physical characteristics are not congruent with their self-identified single race (i.e. White for a Black/White person), or in regions where the crossing of racial lines is unacceptable. Finally, there is the *identification of a new racial group*. In this stage the mixed-race person feels exceptionally committed to their multiracial heritage and wishes to identify as such in all areas of their lives. However, individuals who cannot identify as two or more races or develop a complete sense of belonging to one racial group will likely choose to identify as a new racial group, such as "human."

Kerwin and Ponterotto (1995) proposed a biracial identity model that used age-based stages and asserted that individuals may have both a public and private identity. In addition, this model was the first to acknowledge that biracial individuals may experience rejection from both parent cultures. This model starts at the *preschool* stage, where biracial children

up to the age of five become aware of physical appearance. With the *entry to school* stage, exposure to other children introduces the pressure to identify as monoracial. In the *preadolescence* stage, social meanings become more sophisticated, taking into account physical characteristics, culture, ethnicity, and religion. When young individuals experience overt or covert racism, sensitivity is heightened and may trigger identity questions. *Adolescence* can bring increased external pressure to clearly express a monoracial allegiance. *College/young adulthood* stage continues to bring pressure to monoracially identify, and the individual may experience a heightened yet isolating awareness of race relations. The *adulthood* stage brings continued exploration in race and culture, which may result in more nuanced self-definitions and a special type of racial flexibility in racial adaptation and understanding.

Rockquemore's (1999) exploration into multiracial identity found that biracial identity development tends to be more fluid than it is static and opined four racial self-identity options. With a *singular or traditional identity* the individual is aware of their parents' monoracial status and consciously decides to exclusively identify as one race. An individual holding a *border identity* understands their biracial status and chooses to highlight this fact by solely self-identifying as biracial. With a *protean identity* the mixed-race person chooses to freely move between racial groups, identifying as biracial in some social contexts and monoracial in others. The *transcendent identity* individual claims no racial identity and ignores racial categorization unless pressured to identify their race. These identification options consider the effects socialization has on racial identity that is often dependent on differing demographic regions and political conventions and ideations.

These biracial identity development models have significantly progressed over time and pointed to the interaction between the individual and the socio-political context. They are imperative in understanding the unique and complex processes for individuals in forming a biracial self-identity. Despite the improvements of RID models for biracial individuals in the 1990s, models that encompass those that are multiracial versus biracial have not been clearly developed and point to a new need in the field.

Psychological Research into Biracial Identity Development

In the research literature prior to the mid-1980s, the term *biracial* was primarily used to mean "more than one race" within groups (e.g. a "biracial sample" indicated the studied population was composed of both White and Black individuals) rather than the experience or characteristics of individuals who came from a biracial background. Additionally, all the studies found looked only at African American and White as homogenous racial categories; other racial/ethnic groups were not represented.

In the late 1980s and early 1990s, the terms *biracial* and *multiracial* became associated with the idea of individual identity. The earliest studies appeared most frequently in feminist-oriented journals. However, while RID quickly became an important theme throughout the 1990s, there were still only a few studies looking at biracial experience. For instance, Kerwin, Ponterrotto, Jackson, and Harris (1993) explored how biracial identity is formed in children using qualitative interviews; Root (1998) offered a preliminary report on a mixed-methods study, *The Biracial Sibling Project*. Both these widely cited studies examine the

variability of the lived experience of being biracial as well as the impact of the larger cultural context, highlighting experiences of racism and the need for a term not imposed from the more dominant culture.

In the 2000s, the research has continued to delve into more specific areas of biracial identity, such as different ethnic identities (e.g. Asian and Hispanic) and gender differences. Rockquemore, Brunsma, and Delgado (2009) note that particularly after the change in the US Census in 2000, new quantitative data sets became available to researchers, leading to increasingly detailed understandings that biracial RID is highly idiosyncratic and contextually influenced. The authors analyze the assumptions that underlie race research, and the ways that biracial individuals illuminate or challenge them. The authors also critique the research generally as created out of the assumptions we make as a culture about race, including race as a social construct and an increased awareness of the impact of experiences of racism and discrimination. In addition, they emphasize that distinction must be made between an individual's racial identity (or self-understanding); racial identification (how others understand and categorize an individual); and racial category (what racial identities are available and chosen in a specific context).

Another major influence recognized in current theory is the cultural differences in conception of the self that some racial identities may bring, as in the interdependent orientation found in many Asian cultures (Lou, Lalaonde, & Wilson, 2011); the individual who is reconciling identities with very different cultural orientations may have a different experience of identity construction overall.

Trends in the research appear to be moving toward redefining the idea of race in line with changing social norms; studying biracial individuals from a variety of racial groups, as well as individuals who come from two minority groups; and developing further understanding of the ways in which cultural context and other identities impact racial identity formation.

Conclusion

Our psychological understanding of biracial identity has been heavily influenced by the socio-political context that surrounds the field. Racial identity models have reflected historical changes, and have shifted focus from the pathology of the biracial individual to the impact of external factors and the intricacies of identity development. Established racial identity models have not been empirically tested, and there is yet to be clear theoretical conceptualization regarding the multiracial individual and the children of the biracial baby boom. Research in this area may be wrought with political ramifications given the racial tensions of our society, but it is important nonetheless for the growing demographic of biracial and multiracial individuals.

Social Class

William Ming Liu[1] and Charles D. Cederberg[2]

[1] *University of Maryland*
[2] *University of Iowa*

Conceptualized and Categorized

Social class may be defined as a social category that differentiates an individual's access to available material resources because of the individual's education, occupation, and income (Liu, 2011). Recent scholarship suggests that, along with objective access to material resources, social class is related to one's subjective perception of relative social-class rank in relation to others within one's settings and context. These ranking processes likely take place across an individual's immediate social circle, local community, and broader society (Piff et al., 2010). Subjective approaches to social class have been shown to be robust variables in research. Health psychologists found, for instance, that asking participants to rank themselves on a social-class ladder about their perceived status was a better predictor of subjective health than variables such as education, income, or occupation.

This contemporary contextually sensitive approach belies the decades of research focused on identifying innate personality differences between the rich and poor. Auld (1952) reviewed a series of studies examining response differences on personality inventories among individuals of different social classes. Middle-class participants scored more favorably than lower-status participants. Furthermore, results from the Berneuter Personality Inventory found lower scores of neuroticism, higher scores of self-sufficiency, and higher scores of dominance among upper-class participants. Individuals from economically underprivileged backgrounds also trended toward personality patterns described as maladjusted. Social-class studies using the Brown Personality Inventory suggested lower-class children scored overall less favorably on traits of insecurity, neuroticism, and irritability. Similarly, the California Test of Personality, Wisconsin Scale of Personality Traits, and Minnesota Multiphasic Personality Inventory showed higher-status children scored more favorably than those of lower-status particularly in domains related to emotional stability.

Likewise, Eysenck (1961) and Eysenck and Eysenck (1970) directly investigated personality differences between social classes. The researchers suggested middle-class individuals

possessed a higher degree of mental stability than those in the lower-working class. Additionally, those in lower classes scored higher in traits of neuroticism and psychoticism. Eysenck (1961) reported lower-class individuals were high in emotional instability and neuroticism. However, tough-mindedness was found to be higher among working-class lower-status participants. Eysenck and Eysenck (1970) later examined personality traits in a criminal population and found higher scores in traits of psychoticism and neuroticism. Other research found upper-class individuals to demonstrate higher intellectual flexibility, endorse less authoritarian values, be more open to change, report higher self-concept, and possess more general positivity about the world (Kohn & Schooler, 1969). Kohn & Schooler (1969) found that individuals from upper-social class backgrounds were more likely than lower-class individuals to endorse valuing self-direction and concern for internal psychological processes compared to conformity and concern for external appearances in childrearing. Rather than identifying the contextual and situational variables related to the individual differences and personality, researchers of that time tended to conflate "lower-class" as synonymous with deviance and vice-versa for those in middle- and upper-social class groups.

Cross-Cultural Considerations of Social Class

Race, gender, and social class have been intimately tied together for centuries to marginalize non-White, male, Christian groups and individuals (Liu, Hernandez, Mahmood, & Stinson, 2006). In mid-twentieth-century research, deviance from White norms and expectations were ascribed to lower-class individuals, particularly pertaining to those from non-White backgrounds. Some researchers described Whites to generally possess "better personality adjustment" when compared to African Americans.

Some scholars of the time recognized racist and sexist attitudes embedded within social structures might facilitate the negative psychological outcomes observed in studies including low self-esteem, rage, and helplessness in systemically disempowered peoples. But the tension between essentialist and contextual considerations of differences continued. For example, Battle and Rotter (1963) investigated the interaction of social class and racial groups for a generalized personality variable called internal-external control attitudes, or the degree of acceptance for personal responsibility. In general, middle-class children significantly endorsed internal control attitudes than lower-class children; however the lower-class Black children significantly endorsed the highest external control attitudes among all groups. Although the researchers were aware that external control attitudes reflected in large part the systemic racism and reduced sense of agency in which these children lived, words used to describe the internally controlled children included positively connoted words such as *mature*, while words to describe those endorsing externally controlled attitudes included *alienated* and engaging in *defensive reactions*. More recently, Twenge and Crocker (2002) conducted a meta-analysis of race differences in self-esteem that might support the influence of a cultural social structure context influencing individual trait variables. The authors found White self-esteem differences compared to Hispanics, Asians, and American Indians to be smallest in childhood and increasing with age, possibly due to the growing awareness and importance people place on social class throughout the life span.

However, Black self-esteem increased relative to Whites over time and was first observed during the 1980s, broadly reflecting the changes in civil rights occurring throughout the country at the time.

Mental Health Disparities and Social Class

Social class has been shown to be associated with various physical and mental-health outcomes. Scholars speculate that social class may predict one's physical and mental health in that there is a gradient wherein the higher one is on the social class and economic hierarchy the individual has better overall health. While it is accurate that those in higher social-class groups may have better access to resources and health care, scholars have challenged the assumption that those in higher social classes are without mental-health concerns. Levine (2006) writes about the negative mental-health outcomes associated with growing up in wealthy, privileged backgrounds. The author discusses pressures for achievement in academic, financial, and occupational domains all contribute to mental-health issues such as anxiety and depression. Additionally, Levine (2006) describes the negative mental-health effects of materialistic value orientations and parents that over emphasize externalized goals in their children related to wealth, material possessions, status, and popularity. Similarly, research on affluent adolescents suggests that there are psychological costs to living in material wealth, and that for some wealthy adolescents part of that cost may be increased addictive behaviors.

Shift to a Contextualized Social Class Personality Perspective

Recent researchers embraced the emphasis on subjective experiences and context as an important factor in explaining social class and the personality traits and behaviors of others. Kraus and Keltner (2013) investigated different attributional styles of individuals from different social classes, hypothesizing individuals from upper-class and lower-class ranks would divergently explain individual attributes of others. Specifically, the authors noted individuals from upper-class ranks are more likely to endorse essentialist explanations (i.e. biological, genetically based explanations for social class) for social class categories. Differences in education and income, common objective indices of social class, were also more likely to be endorsed as biologically derived by individuals from higher social class backgrounds. Individuals from upper-class ranks were also more likely to endorse beliefs in meritocracy and in a just world. Conversely, lower-class individuals were more likely to endorse that social class was changeable and derived from external circumstances. These contextual explanations provided by individuals from lower-class backgrounds has been hypothesized as a means for explaining the decreased sense of control lower-class individuals feel in their daily lives (Kraus, Piff, & Keltner, 2009). Additionally, Kraus, Cote, and Keltner (2010) found that these external explanations more readily associated with individuals from lower-class backgrounds also enabled an increased capacity to demonstrate empathic accuracy and judge the emotional states of others. Piff et al. (2010) hypothesized lower-class individuals respond to the feelings of decreased sense of control, reduced

access to resources, and increased exposure to potential threat by demonstrating more prosocial behaviors as a strategy to adapt to their hostile environment. Across four separate studies, participants identified as lower in social class demonstrated more prosocial behaviors including generosity, charity, trust, and helpfulness than participants with higher social class backgrounds.

Other research illustrates the importance that subjective social class contributes to social-class perspective of others' characteristics. Individuals from upper-classes are commonly perceived as possessing greater competence, self-discipline, sophistication, and desirability while the opposite holds for individuals from poor backgrounds. Kraus et al. (2009) found when participants rated themselves high on a social-class ladder representing society, they were more likely to attribute external circumstances as based on individual traits or dispositions compared to lower-class ranked participants. A later series of seven studies (Piff et al., 2012) showed across various experimental and naturalistic settings individuals from higher-class backgrounds engaged in more unethical behaviors such as breaking the law while driving, engaging in unethical decision making, taking valued goods from others, lie in negotiation situations, cheat to increase potential rewards, and endorse unethical behaviors at work than individuals from lower-class backgrounds as a result of higher endorsed attitudes towards greed.

Finally, Jost (Jost, Banaji, & Nosek, 2004) and colleagues have shown via system-justification theory that being from a social-class position (e.g. lower-social class) may mean that the individual might vote for policies that are against the individual's best interest. In system-justification theory, the lower-social class individual is within a dominant system and to rationalize the individual's lower-social class situation, she/he may subscribe to the beneficence of the system. This within group variability suggests that the categorical approach (e.g. grouping individuals in to social-class groups like middle-class) has limited utility. From the research there is meaningful and significant variability in personality and individual differences related to social class and classism. Moving beyond essentialist theories of innate differences due to social-class group is important for future scholarship. Social class, socioeconomic status, and classism are contextual and situational but impact the worldviews, values, and personality of individuals.

Cultural Encapsulation

Jude Bergkamp and Matthew Ponsford

Antioch University Seattle

In our everyday life, we naturally seek homogeneity for comfort and predictability by avoiding difference and change. How much we can control our exposure to difference and change can vary, depending on factors such as politics, social privilege, socioeconomic status, and profession, just to name a few. Counselors are no different. In 1962, C. Gilbert Wrenn coined the term *cultural encapsulation* to emphasize the natural tendency of counselors to be bound by culture and time to avoid difference and change that results from cross-cultural exposure and societal development.

The term *encapsulation* conjures up the image of a cocoon or shelter that is slowly developed over time to preserve and protect attitudes, beliefs, and assumptions (Heppner, Wang, Heppner, & Wang, 2012). Wrenn stated "...we protect ourselves from the disturbing reality of change by surrounding ourselves with a cocoon of pretended reality – a reality based upon the past and the known" (1962, p. 445). The process can happen in an unconscious manner, pulling from a human need for self-preservation, and may be implicitly agreed upon across counselors and the field in general. Wrenn (1962) warned that encapsulation allows the counselor to hold cultural assumptions and stereotypes while simultaneously being guarded from the uncomfortable confusion of cultural difference and a threatened worldview. He further warned that this process could have negative effects on the quality of counseling.

Wrenn (1962) discussed three variations on cultural encapsulation in his original essay. The first is "the tendency to be surprised or even unbelieving regarding changes in truth" (p. 446). Counselors can gradually establish a belief in stable truths based on cultural and generational factors that are hard to modify in the face of change. The danger is that the counselor is not able to adapt to change and may generalize their beliefs to the clients' experience despite cultural or generational differences. The second variation is "the cushioning of the counselor in some academic cocoons which have little reference to our total culture" (p. 447). While counselors develop shared assumptions of human behavior during training and professional practice, these assumptions may not be applicable to all settings

and situations. The third variation is "the assumption that the counselor may safely draw upon his own education and vocational experience in counseling" (p. 448). The counselor inevitably refers to his or her past when attempting to assist with the client's future, failing to account for the rapid rate of current change.

Furthering the concept in 1985, during the War on Drugs and the ever-present fear of nuclear war, Wrenn identified two common reactions to societal changes that can lead to encapsulation: hopelessness and denial. Hopelessness about the world can manifest in thoughts that the problem is too big for an individual to influence, too advanced to stop, or too complex to understand. Denial of the reality of change can take the form of thoughts that the change cannot be true, it is highly exaggerated, or that it will just get better with time. Hopelessness and denial can serve as a self-constructed cocoon to protect the individual from the stress and ambiguity change elicits.

In addition, Wrenn asserted that cultural encapsulation permits the counselor to be insensitive to cultural variations on reality, perpetuate cultural stereotypes without proof, avoid consideration of alternative worldviews, and remain complacent in their own cultural values. Consequently, counselors can believe that the Western model of mental health applies to all cultures and that existing counseling techniques should work across individuals, and may risk pathologizing culturally different individuals and forcing treatments that could be harmful. This dynamic results in a decrease in the effectiveness and credibility of the field.

Sanchez (2001) describes a paradox in treating clients who are culturally different from the counselor, in that the counselor is ethically bound not to work with clients outside of their competence, but it is impossible to refer every client with whom the counselor is culturally different, nor is it possible to be knowledgeable in the intricacies and nuances of every culture. The first step in avoiding encapsulation is recognizing and acknowledging one's own cultural background and subjective viewpoint. Rather than making broad assumptions about clients based on gross stereotypes or attempting to minimize between-group differences, Sanchez suggests that broad cultural references may be treated as a point of inquiry, or an invitation to a cultural dialog.

Despite its revisions over the years, the APA Ethical Principles and Code of Conduct itself is encapsulated within the beliefs, practices, and assumptions of a specific majority culture (LaFromboise & Foster, 1989). While the document has been improved since these criticisms were made, it still lacks the language called for by Pedersen and Ivey (1987), who recommended that the code speak to the need for recognition of socio-cultural differences in all endeavors of research, writing, and practice.

The concept of cultural encapsulation has been utilized in the field of multicultural counseling for over five decades to signify the innate risk of stereotypes and ethnocentrism (LaFromboise & *Foster*, 1989; Pedersen, Crethar, & Carlson, 2008), but it has yet to be empirically examined. Since 1962, the field of psychology has come to an agreement that awareness and understanding of cultural differences is an essential component of counselor training and practice. Research in the field has also seen many advances in our knowledge of how human difference affects behavior (Jim & Pistrang, 2007). Yet, with the increasing changes in globalization, technology, and identity, the concept of cultural encapsulation may be more applicable, and potentially problematic, today than ever before.

Machismo

Oscar Fernando Rojas Pérez[1] and Alejandro Morales[2]

[1] *University of Missouri–Columbia*
[2] *California State Polytechnic University, Pomona*

Machismo is a concept that continues to defy a clear definitional description. Vaguely, *machismo* denotes a "typical" masculine gender role behavior exhibited by Latino men, in particular men in Mexican culture (Torres, Solberg, & Carlstrom, 2002). Definitions of *machismo* vary from "an ethos comprised of behaviors prized and expected of men in Latin American countries" (Panitz, McConchie, Sauber, & Fonseca, 1983) to "Mexican men's manifestation of perceived male characteristics, both positive and negative" (Arciniega, Tovar-Gamero, & Sand, 2004). Traditional perspectives and interpretations of *machismo* are associated with negative characteristics of sexism, chauvinism, and hypermasculinity. Stereotypical traits associated with the concept include: violent, aggressive, womanizing, controlling, rude, prone to alcoholism, emotionally withdrawn, and domineering through intimidation. Moreover, traditional views and characteristics used to define and describe *machismo* are one-dimensional and restrictive, disregarding positive aspects of Latino male behavior.

Contemporary definitions challenge the one-dimensional and negative descriptions of *machismo*, highlighting positive behaviors and descriptors that resemble qualities associated with the word *caballerismo* (Arciniega et al., 2008). *Caballerismo* refers to chivalry, dignity, honor, respect, nurturance and protector (Arciniega et al., 2008). *Caballeros* are family centered, honor and protect the *familia*, and are emotionally responsive and communicative. Ultimately, *machismo* is a multidimensional concept, operationalized along a continuum of not only individual power and hypermasculinity but also subtle covert beliefs and attitudes related to social responsibility and emotional connectedness.

The origins of *machismo* are thought to derive from the Spanish conquest and the conquistadores' exploitation of natives. *Machismo* is said to be the by product of the endured humiliation experienced by indigenous men during the conquest, given the violence and subjugation that occurred during colonization (Hardin, 2002). In particular, as the invading conquistadores systematically violated indigenous women, they instilled European racial superiority over indigenous men who were not able to protect their female kin (Hardin, 2002).

Claims are made that during the colonization period, in order to compensate for physical and cultural defeat, indigenous men took on macho attitudes and behaviors as an attempt to regain some form of dignity and honor after their emasculation and feeling of inferiority, powerlessness, and defeat by the conquistadores (Hardin, 2002). The term *machismo* is believed to originate from the Spanish *macho*, indicating "male." The word "*macho*" is said to have roots in the classical Nahuatl language of the Aztecs of central Mexico, indicating "image" or "reflection of myself" (Hardin, 2002). Similar to the term *machismo, caballerismo* originates in the Spanish word for horse and horseman – *caballo* and/or *caballero* (Arciniega et al., 2008). Thus, the word *caballero* referenced a land-owning Spanish gentleman of high status and master of *haciendas* (i.e. ranches) (Arciniega et al., 2008). *Caballerismo* also refers to a code of masculine chivalry, stemming from the original Latin root *caballus*. Over time, the development of the term *caballero* evolved to signify a Spanish gentleman displaying appropriate and respectful behaviors, adhering to an ethical code of chivalry.

Machismo: An Overview

Machismo can be understood as a socially constructed, learned, and reinforced set of behaviors and customary roles comprising the content of male gendered roles in Latino culture. As a result, *machismo* can be understood as impacting identity and behaviors. Simply, *machismo* is the socially expected and approved way of being a Latino man. Broadly, *machismo* has been understood and portrayed as a cultural and social ailment believed to cause violence and alcoholism (Arciniega et al., 2008). Likewise, *machismo* is widely regarded as culturally specific behavior associated with chronic poverty, laziness, and other ethnic and class-based prejudice (Torres, Solberg, & Carlstrom, 2002). In everyday life, the system of *machismo* is reinforced through ideals and practices of fearlessness, power and control over women, and sexual dominance.

Traditional practices that perpetuate *machismo* are associated with behaviors that physically and psychologically harm women in the process of proving one's manhood (Pardo et al., 2012). However, modern practices that are positive conceptions of *machismo* are associated with standing up for one's family, meeting kinship obligations such as financial support, and protectiveness toward one's family (Estrada & Arciniega, 2014). Most recent examples of *machismo* date back to the ethnoindustry launched during the Golden era of Mexican cinema during the 1950s and the Chicano movement of the 1960s and 1970s (Falicov, 2010). Although the Golden era of Mexican cinema and the Chicano movement perpetuated stereotypes of *traditional machismo* by making the Mexican *bandido* (bandit) an iconic cinema figure and by initially sidelining women in the struggle for Mexican American civil rights and empowerment, it also created space for scholars to push for a more complete and nuanced understanding of *machismo* and Latino cultural norms (Falicov, 2010). Having a more complete understanding of *machismo* may expose younger Latino men to fluid gender roles during their upbringing, thereby experiencing less cultural and social pressure to assert their masculinity by exemplifying dominance over women.

The literature supports the notion that *machismo* is a multidimensional construct comprising of both *traditional machismo* and *caballerismo* behaviors and characteristics

(Arciniega et al., 2008). The dimension of *traditional machismo* is related to aggression, antisocial behaviors, hypermasculine traits such as sex-role dominance, high levels of alexithymia, and more wishful thinking as a coping mechanism. However, the dimension of *caballerismo* is related to affiliation, ethnic identity, problem-solving coping strategies, emotional responsiveness, and elements of nurturance and family centeredness. Additional traits associated with *caballerismo* include assertiveness, sincerity, and responsibility. Not surprisingly, *traditional machismo* has been linked to lower levels of psychological well-being, life satisfaction, and dysfunctional coping approaches such as drinking and fighting (Arciniega et al., 2008). Further, *traditional machismo* has been shown to relate to more negative images associated with *machismo*. Contrary, research related to *caballerismo* identifies higher levels of psychological well-being, life satisfaction, positive self-esteem, and ability to understand one's own and the emotions of others (Arciniega et al., 2008). Latino men who exhibit *traditional machismo* traits and attitudes are prone to higher levels of depression and negative attitudes toward mental health treatment compared to men who display characteristics and behaviors of *caballerismo* (Fragoso & Kashubeck, 2000). Moreover, there is compelling evidence that *traditional machismo* leads to lower levels of marriage satisfaction and higher levels of stress. On the contrary, *caballerismo* has been documented as a protective factor for Latino men serving as an outlet for emotional expression and a guard against stress. These findings presented provide a critical step in empirically understanding the construct of *machismo* and how it operates in the lives of Latino men.

The Future of Machismo

The unique historical context of much of Latin America combined with the manifestation of Latino cultural values and scripts, make *machismo* a Latino male cultural-specific gendered experience, in particular with Mexican men. The existence and longstanding and deeply engrained set of beliefs, behaviors, and attitudes associated with Latino male masculinity posit *machismo* as a negative stereotype dominated by negative traits. However, most recent research and argument is that of *machismo* as multidimensional, consisting of both negative (traditional *machismo*) and positive traits (*caballerismo*). Further, exploring *machismo* from a multidimensional perspective will broaden the set of traits of interpersonal characteristics and personal lived experience with oppression, prejudice, marginalization, and social injustices. Having a more comprehensive understanding of *machismo* will filter some of the negative traits and highlight the more positive. Moreover, exploring how *machismo* operates in the lives of not just heterosexual men but also gay men will also allow for a more inclusive and complete understanding. Thus, current and future ideology of *machismo* should be extended to include factors such as socioeconomic status, women's advancement and participation in public arenas and the workforce, male responsibility in domestic spaces, and level of education to explain some of the variance. Given the varying stance on the construct of *machismo*, the challenge moving forward is to better understand how *machismo* may manifest itself in the lived experiences of diverse groups of Latino men, the systems of *machismo*, and *machista* attitudes.

Marianismo

Alejandro Morales[1] and Oscar Fernando Rojas Pérez[2]

[1] *California State Polytechnic University*
[2] *University of Missouri–Columbia*

Overview

Marianismo was first introduced in the early 1970s in the field of political science to describe Latinas' gender role expectations and norms (Stevens, 1973). Psychologists and other social science scholars have since studied marianismo to better understand its impact within the Latino cultural value system. This line of research has shown that marianismo is associated with negative mental-health outcomes, gender-based violence, and risky sexual behaviors (Moreno, 2007; Pina-Watson, Castillo, Ojeda & Rodriguez, 2013). According to its definition, marianismo expects Latinas to be submissive to men, humble, endure sacrifices and suffering to maintain the family (Castillo, Perez, Castillo, & Chosheh, 2010). Another important component of marianismo is to see the Virgin Mary as their role model. Hence, Latinas must to stay pure and asexual until marriage (Castillo & Cano, 2007).

Marianismo and machismo have distinct differences within the gender role literature. For example, machismo is characterized by sexism, chauvinism, and hypermasculinity. Stereotypical machismo behaviors include, violent, aggressive, womanizing, controlling, rude, prone to alcoholism, emotionally withdrawn, and domineering through intimidation (Arciniega et al., 2008). Conversely, marianismo is about restricting Latinas from engaging from sexual behaviors before marriage and ascribed to more traditional gender roles such as remaining pure until marriage and being in charge of child care (Castillo & Cano, 2007). Scholars have questioned the sexism perpetuated within marianismo and have asked for more empowering gender roles. *Hembrismo* is less a common gender role and more widely accepted by Latina feminists because characterizes Latinas as strong, resilient, and confident women (Ruiz, 2005).

Scholars studying Latinas/os argue that the cultural value of *familismo* is influential in the behaviors of Latina girls and women (Rafaelli & Ontani, 2004). Familismo draws from a collectivistic worldview and is defined as a person's strong attachment and commitment to their immediate and extended family (Triandis & Trafimow, 2001). The needs of the family

take priority over the individual's. Within the Latino culture, familismo expects women to remain close to their families, be supportive in multiple ways, procreate, take care of their children, and take responsibility of household chores (Castillo, Perez, Castillo, & Chosheh, 2010). Qualitative studies have provided insightful information on how marinismo may be transmitted in families. In a study looking at marianismo and sexual activity among immigrant Salvadorean mothers and daughters living in Canada, it was found that mothers actively discourage their daughters to engage in sexual intercourse and mainstream women's sexual health activities (Carraza, 2013). The author suggested that perhaps the intersections of Latino culture, gender roles, and religion may have influenced both mothers and daughters to value of female chastity.

Owing to the importance of marianismo in the literature, measurement studies have led to the development and publication of the Marianismo Beliefs Scale (MBS; Castillo, Perez, Castillo, & Chosheh, 2010). The MBS consists of 24-item scale consisting of five subscales, family pillar, virtuous and chaste, subordinate to others, self-silencing to maintain harmony, and spiritual pillar. Each item is scored using a four-point Likert scale ranging from 1 strongly agree to 4 strongly disagree. The MBS currently has an adult and adolescent version, and may be used with both male and female participants. Studies looking at the psychometric properties of the MBS have concluded that the scale has acceptable reliability coefficients and convergent and discriminant validity with college and adolescent samples (Castillo, Perez, Castillo, & Chosheh, 2010; Sanchez, Whittaker, Hamilton & Zayas, 2016). Another instrument used to assess this gender role in Latinas is the Guzmán Marianismo Inventory (GMI; Guzmán, 2011). The GMI has 18 items using a four-point Likert scale ranging from never true of me to always true of me. The inventory has three subscales including, traditional marianismo, familismo, and servant leadership. Despite the strong psychometric properties of the GMI, it is not widely used in the Latina/o Psychology literature. Research on marianismo has flourished and psychometrically sound instruments are readily available for scholars interested in this topic. The following section provides a brief synopsis on research about marianismo and its association with academic performance, mental-health outcomes, and risky sexual behaviors among Latino diverse samples.

Psychosocial Correlates of Marianismo

Academic Achievement

Studies focusing on Latina/o cultural values have led to important findings. Owing to their significant representation in the US educational system, researchers have investigated how cultural values may influence Latinas/os succeeding academically. Positive aspects of marianismo have been found to be a strong predictor of academic motivation. In a study looking at the influence of marianismo on the academic achievement among Latina adolescents, it was found that the spiritual and family pillars subscales of the MBS were significantly correlated to academic motivation (Rodriguez, Castillo, & Gandara, 2013). In their study, Rodriguez and colleagues (2013) argue that based on their results having a strong connection with a higher power and familial ties assisted Latina adolescents in their academic pursuits. Other studies suggested that marianismo is not a predictor of academic success

among Latina students. In a study with adult Latina women, Melendez (2005) found no significant relationships between marianismo and level of education, acculturation, social economic status, and conflict. The contradicting evidence about marianismo and academic achievement deserves serious attention, as Latinas are outnumbering Latinos in attending and graduating from college (Zarate & Burciaga, 2010).

Depression

The association between marianismo and psychological distress has been the focus of the vast majority of the research on this topic, leading to mixed results. In a study with Mexican American preadolescent girls, Sanchez and colleagues (2016) found no relationship between marianismo beliefs and depressive symptoms. The authors argued that in traditional Latino families, adolescent girls are conditioned to follow the rules and not ask questions. Thus, they may not be aware of marianismo or how it may affect their psychological well-being. Conversely, Pina-Watson and colleagues (2013) found a strong positive relationship between marianismo beliefs and depressive symptoms in a sample of Mexican American college women. They also reported that this relationship was mediated by parental conflict. Latinas in higher education often see how college facilitates their explorations of ethnicity, cultural values, sexuality, and other dimensions of self-identity. These processes may often create crises that may lead to psychological distress. Latina college students struggle between wanting to fully express their multiple identities and what is expected from their families, especially their parents. Lastly, married adult Latina women who endorse marianismo behaviors such as self-silencing and self-sacrificing report significant higher levels of depression (Vazquez, 1998). Owing to the alarming rates of depression and suicidality, especially among young Latinas, future studies on marianismo must continue to disentangle how gender roles may influence the psychological well-being of this group of women (Romero, Edwards, Bauman & Ritter, 2014; Zayas, 2011).

Sexual Behaviors

The scholarship on the effects of marianismo on sexual behaviors is increasing. Studies on gender socialization show that Latinas are brought up with stricter rules about sexual behavior, desire, and satisfaction. The rigid messages regarding female sexuality may lead Latinas to potentially engage in risky sexual behaviors or not have fulfilling sexual relationships with their partner (Hussain, Leija, Lewis, & Sanchez, 2015; Rafaelli & Ontani, 2004). In a study looking at sexual behaviors among Latina preadolescents, researchers found that negative aspects of marianismo (i.e. being virtuous/chaste, maintaining virginity) were negatively associated with sexual attitudes and precursor behaviors (Sanchez, Whittaker, Hamilton, & Zayas, 2016). Similarly, other scholars argue that Latina women may experience internal conflicts between the rigid sexual morals instilled from their families with their sexual pleasure and satisfaction leading to psychological distress (Hussain, Leija, Lewis, & Sanchez, 2015). Sexual health is critical in the prevention of sexually transmitted

infections among Latinas and other women of color. Marianismo remains an important gender role mechanism that needs to be included in future prevention and interventions programs targeting sexual behaviors in Latinas living in the United States.

Future Directions

The scholarship on marianismo is growing and more studies are urgently needed. As the Latina/o population continues to grow and becomes more diverse, our understanding of gender roles remain important variables to consider in future research. The goal of such studies will be to provide innovative ways to develop and test culturally targeted interventions for Latinas across different ages and level of education.

Visible Racial/Ethnic Group (VREG)

Donelda A. Cook[1] and Jeffery Scott Mio[2]

[1] *Loyola University Maryland*
[2] *California State Polytechnic University*

The term *visible racial/ethnic groups* (VREGs) was coined by Janet E. Helms and Donelda A. Cook in 1988, as alternative nomenclature for African, Latinx, Asian and Pacific Islander, and Native/Indigenous Americans (ALANA). The field of multicultural psychology has consistently made language changes for designating the various racial/ethnic groups in the United States. During the 1960s and early 1970s, the psychological research examining racial differences in populations referred to research participants as "Whites" and "non-Whites." In the late 1970s, there was movement away from the term, "non-Whites," as it suggested that persons of African, Latin, Asian, and Native/Indigenous Americans descent were only recognized in being counter to "Whites" as the dominant racial group, and results of any differences from Whites were interpreted as deficits. Thus, the terminology of "racial/ethnic minorities" came in use, acknowledging racial/ethnic group people as fewer in number than White people in the United States, but also acknowledging that they reflected valid cultural identities and worldviews stemming from countries of their ancestral origins, separate and apart from White European cultural identities.

Helms and Cook began using the term "visible racial/ethnic groups" (VREGs) in place of racial/ethnic minorities, as the respective minority and majority status designations for VREGs and Whites continued to disempower and characterize VREGs as deficient in comparison to White societal standards. Minority and majority labeling reinforced existing socio-political and socioeconomic racial differences in the United States. Even in locations where Whites are in the numerical minority, and either African, Latina/o, Asian and Pacific Islanders, or Native/Indigenous Americans are the numerical majority, Whites maintain the power and privileges of the "majority" in educational, economic, legal, and political societal practices and institutions. The potential exists for VREG and White individuals to internalize the power dynamics inherent in the designated use of the identity labels minority and majority, thus perpetuating societal inequities.

Helms and Cook also considered "visible racial/ethnic groups" as an alternative to the term *people of color* (POC). People of color recognizes that in the United States socio-racial group designations are assigned to persons based on differences in visible physical characteristics such as skin color, hair texture, eye shape, and other facial features. However, language use is another visible distinguishing characteristic for Latina/o persons that the term POC does not capture, particularly for White Latina/o individuals. White-skinned Latina/o individuals may be subject to similar discriminatory attitudes and practices as individuals of African, Asian, Pacific Island, and Native/Indigenous American descent, as their language accents, preferences, and fluidity of one or more languages spoken in the home or community, and English-language fluency are visible identifying characteristics, which distinguish them from "White European Americans."

In the 1990s, as researchers began recognizing and investigating within racial/ethnic group differences, convenience terms like VREG, ALANA, and POC connoting the larger racial/ethnic group designations used by the US Census Bureau, did not adequately reflect the variability within African, Latina/o, Asian and Pacific Islander, and Native/Indigenous Americans. With an increase in immigrants from VREG countries, psychological research benefited from an increase in participants from separate racial/ethnic groups that provided the opportunity to study within group differences rather than between racial/ethnic group differences. Differences have been found to exist in the variety of national ancestries and countries of birth, length of residence in the United States, and migration or immigration history and generational status, within each of the aforementioned racial/ethnic groups. For example, the racial/ethnic identification term of "African Americans or Blacks" used by the US Census Bureau, assumes similarities between persons of African descent who voluntarily immigrated to the United States as adults, those whose ancestors were involuntarily brought to the United States and sold into slavery, and Afro-Caribbeans whose ancestors either migrated to a Caribbean country or had differing history of enslavement in those countries from the United States. These historical racial histories, social-cultural and political backgrounds of present-day "African Americans or Blacks" have implications for various within racial/ethnic group differences. Thus, the use of the term visible racial/ethnic groups began to diminish in the psychological literature.

The use of VREGs also diminished with increasing numbers of persons from multiracial backgrounds and recognition of the importance of intersecting identities. The 2000 US Census began allowing respondents to designate more than one race. Thus, the term VREGs did not capture multiracial and multiple ethnicity identities and the corresponding intersecting cultural characteristics of persons from more than one racial/ethnic group. While the demarcation of *visible* in the term *visible racial/ethnic group* is still relevant to multiracial and multiple ethnicity identities, as physical features and language use may still be visible distinguishing identity characteristics, it does not capture the multidimensional constructs involved in multiracial identity. For instance, Harris and Sim (2002) examined the complexity of assessing a single racial identity among multiracial adolescents. They found adolescents to report "multiple context-specific racial identities" along several contextual dimensions. Harris and Sim describe "internal racial identity" as how one self-identifies one's race, which may vary across contexts of social environments (e.g. with family, with peers, in school), "external racial identities" as how observers perceive that same individual's race, and "expressed racial identities" referring to the words and

actions used toward individuals based on observers' attitudes about that individual's perceived race. While the term *visible* remains relevant in how an individual sees one's self and how others see that individual, the identifying racial designation is fluid, and the fluidity is based on both the individual's identification with one's ancestral cultural values, behaviors, and worldviews and the individual's response to internalized racism or socialized negative conceptions of one's self – and other – identified racial group(s).

While the term VREG may not capture variations within each of the identified racial/ethnic groups, it still remains an important distinction between VREGs and the European American/White population. When an immigrant comes from Eastern Europe, the immigrant is not immediately recognized as an immigrant if he/she does not dress fundamentally differently from their American counterparts. However, when an immigrant comes from Africa, Latin America, or Asia, or when Native/Indigenous Americans are in a city, they are immediately recognized as different from their White American counterparts. The expression "off the reservation" was a racist term directed at Native/Indigenous Americans who were not confined to a reservation, meaning that they were not where they were "supposed" to be. The capture of Native/Indigenous American children for the purposes of forcing them into boarding schools to "beat the Indian" out of the children without their parents' permission was based on the visual identifiability of these children (Tafoya & Del Vecchio, 2005). The internment of Americans of Japanese descent was a racist act, as the United States was at war with Germany and Italy as well as with Japan in World War II, but neither Americans of German nor Italian descent were subjected to mass incarceration as the Americans of Japanese descent were because German and Italian descent individuals were not visibly distinguishable from other White Americans (Mio, Nagata, Tsai, & Tewari, 2007). In recent years, the harassment of Americans of Latin American descent due to immigration status is largely based on the visual identification of those who "look" Latinx (Provine & Sanchez, 2011). Certainly, the injustice of "driving while Black" or "driving while Brown" is based on the visual distinction of Americans of African and Latin American descent from their White American counterparts (Mio, Barker, & Rodriguez, 2015). Mio et al. (2015) quote a student of theirs, who was an African immigrant driving in his neighborhood:

> The first week I arrived in this country, I was stopped by the police. He said I matched the description of someone spotted with a gun. He searched me and found nothing. I then inquired what the description was. The man they were looking for was Hispanic. The only matching aspect of our descriptions were that we were both wearing blue jeans. (p. 190)

Obviously, if this student were driving, the police could not see that he was wearing blue jeans, so the only reason why they stopped him was that he was identifiably Black.

Conclusions

VREG was a historical term used to distinguish persons of color from their White counterparts in the United States. This term was initially used for research purposes to determine the degree to which certain generalizations could be made about POC, who were visually

distinguishable from White individuals, but because the populations to which this term was referring became more and more complex due to immigration from a wider and wider range of individuals, use of this term became less in vogue. However, when discussing racism, it still is a useful term, as people of color are visually identifiable from ethnic White immigrants and still experience discrimination and racism based on this visual identifiability, such as in the experience of "driving while Black," "driving while Brown," and immigration status suspicion.

Cross-Cultural Emotional Expression

Hyisung C. Hwang[1] and David Matsumoto[2]

[1] *Humintell*
[2] *San Francisco State University and Humintell*

Emotion

Emotions are transient, biological, psychological, and sociological reactions to events that have consequences for our well-being and that potentially require immediate actions for survival. Emotions are immediate reactions to meaningful stimuli, are biologically resident, and are products of the evolutionary history of human beings. One class of emotions is called biological or basic emotions (Matsumoto & Hwang, 2012). This type of emotion entails immediate actions that are tied to physiological responses, expressive behaviors, and cognitive processes. These emotions are elicited along with physiological responses from the central and autonomic nervous systems. They are psychological because they involve specific mental processes required for the elicitation and regulation of response and direct mental activity, and they motivate behavior. These emotions are social because they are often elicited by social factors and have socially communicative meaning when triggered.

Emotions are rapid information processing systems. Situations related to survival such as birth, battle, death, and seduction have been present throughout our evolutionary history, and emotions aided in adapting to problems that arose rapidly with minimal conscious cognitive intervention. If we did not have emotions, we could not make rapid decisions regarding whether to attack, defend, flee, care for others, reject food, or approach something useful. For example, in a situation in which a person's friends sees his/her friends in the path of a speeding car and screams to alert them, that immediate reaction may be more efficient for his/her friends to escape from danger than describing the danger verbally. Another example involves the emotion of happiness, which is a core positive emotion that is crucial for well-being and social relationships. Smiling often immediately reduces the tension in social interactions with strangers, and happiness is the easiest way for people to express satisfaction. When a friend smiles after tasting something her friend has cooked, the cook no longer feels anxious about the success of her dish. Smiles often

mean no opposition. When a new neighbor smiles at the established neighbors, they tend to relax and feel that the newcomer is not a threat.

Research on Emotional Expressions on the Face

Conducting research in the field of emotions is not easy because doing so requires the presence or creation of factors and conditions to elicit targeted emotions, and manipulating the contexts to do so is not always possible or easy. Therefore, there is no perfect experimental context for producing emotions in research. Yet there has been a large number of studies that have demonstrated that the facial expressions of anger, contempt, disgust, fear, happiness, sadness, and surprise are universally produced when emotions are elicited spontaneously.

The face is one of the important and complex ways of expressing emotions, and one of the important original studies related to the universality of emotional expressions was conducted by Friesen (1972). In Friesen's cross-cultural study, 25 American and Japanese participants watched neutral and highly stressful films (first episode: body mutilation, second episode: sinus surgery) while their faces were recorded. The coding of the spontaneous facial behaviors that occurred indicated that the American and Japanese participants displayed emotions (e.g. disgust, fear, sadness, and anger) similarly when they were alone, which was assumed to be not affected by social influence. This study provided pioneering evidence that facial expressions of emotion were universally produced when emotions were spontaneously elicited.

Another representative production study was conducted in a naturalistic context. Matsumoto and Willingham (2006) examined the expressions of 84 judo athletes from 35 countries at the 2004 Athens Olympic Games, and reported that the first immediate emotional reactions on the faces of winners and losers at the completion of their final medal match were consistent with the prototypical expressions of the basic emotions. In particular, winners displayed genuine smiles while losers displayed negative emotions such as sadness, disgust, or anger. Genuine smiles are smiles that involve not only the smiling muscle (zygomatic major), which raises the lip corners, but also the muscles surrounding the eyes (orbicularlis oculi), which raise the cheeks, thin the eyes, and narrow the eye cover fold; many studies have shown that only these types of smiles are correlated with the experience of positive emotion (see Ekman, Davidson, & Friesen, 1990 for a review). In contrast, nongenuine smiles only involve the muscles around the mouth, and not the eyes (Ekman, & Friesen, 1978).

Although there were many other cross-cultural studies of facial expressions of emotion, this Olympic study was compelling for several reasons. The results were based on spontaneous, not posed, expressions. Many previous studies often had to deal with variations in basic emotions when testing posed expressions rather than using ones naturally produced in an appropriate emotional context. Also, this cross-cultural study included individuals from various countries at the Olympic games. Olympic matches can be considered a special situation, but they are part of everyday reality in signifying competitions among people, so the emotions of winners and losers of the Olympics are not different from winners and losers of any competition. The findings were meaningful

given that previous research documenting the universality of facial expressions of emotions had been mainly tested in laboratories, not in the field.

Emotional Expressions and Culture

Human culture is a unique meaning and information system, shared by a group and transmitted across generations (Matsumoto & Juang, 2017). One of the major functions of culture is to maintain social order, so culture creates rules, guidelines, values, and norms concerning the regulation of emotion. Unique human cognitive abilities (i.e. language, memory, and abstract thinking) allow cultures to elaborate on human emotions by facilitating the construction of culturally based emotions and their associated meanings.

Cultural display rules (and cultural decoding rules; Matsumoto & Ekman, 1989) are cultural norms and standards that socially guide how to behave and react in social contexts. These rules help us manage the appropriateness of emotional displays in social situations when there is the need to manage the appearance of certain emotions in particular situations. For example, in most cultures, laughing and giggling at a funeral ceremony is considered to be socially undesirable (Matsumoto, 1990). Display rules outline when, where, and how particular expressive behaviors should be displayed, and the rules vary depending on communities, societies, countries, contexts, and interactants. However, variation in cultural display rules does not mean that there are no commonalities. The variation is invaluable because it aids us in understanding how our spontaneous emotional reactions interact with cultural norms to manage expressions that facilitate the ability to develop social relationships.

There are six ways in which display rules can act to modify emotional expressions: (1) Express less than actually felt (Deamplification), (2) Express more than actually felt (Amplification), (3) Show nothing (Neutralization), (4) Show the emotion but with another emotion to comment on it (Qualification), (5) Mask or conceal feelings by showing something else (Masking), (6) Show an emotion when one does not feel it (Simulation). Because we gain knowledge about display rules directly and indirectly in our social lives, we naturally come to know how to manage our immediate emotional reactions. For that reason, emotions can be both universal and culture-specific. These rules are learned early and dictate how the universal emotional expressions should be modified in each culture according to the social situation. By adulthood, these rules are automatic, having been very well practiced.

In a study of display rules by Matsumoto (1990), American and Japanese participants saw two examples of six universal facial expressions of emotion and rated the appropriateness of displaying each in eight social contexts. Americans rated some negative emotions in ingroups, and happiness in outgroups, more appropriate than did the Japanese. The Japanese, however, rated some negative emotions as more appropriate to outgroup members. These findings indicated that members of collectivistic cultures (e.g. Japan) would be discouraged from expressing potentially threatening negative emotions to their ingroups, and potentially bonding positive emotions to their outgroups, while there would be no such tendency for members of individualistic cultures (e.g. the United States).

Application of Display Rules: The Display Rule Assessment Inventory

The Display Rule Assessment Inventory (DRAI) is a measure assessing behavioral responses based on the six response alternatives (discussed above) when people experience different emotions with family, friends, colleagues, and strangers (Matsumoto, Takeuchi, Andayani, Kouznetsova, & Krupp, 1998; Matsumoto, Yoo, Hirayama, & Petrova, 2005). The DRAI has been tested in over 30 countries, examining universal and culture-specific aspects to display rules, and linking the cultural differences to culture-level individualism (vs. collectivism). Despite the large potential range of scores, most countries' means on overall expression that were self-reported suggested a universal norm for the management of emotional expressions. Individuals of all cultures had a display rule norm for greater expressivity toward ingroups than toward outgroups, indicating another universal effect. Collectivistic cultures were associated with a display rule norm of less expressivity overall than individualistic cultures, suggesting that overall expression management for all emotions was central to the preservation of social order in these cultures. Individualism was also positively associated with higher expressivity norms in general, and for positive emotions in particular. Individualism was positively associated with self-reported expressions of all emotions toward ingroups, but negatively correlated with all negative emotions and positively correlated with happiness and surprise toward outgroups.

A more recent study (Hwang & Matsumoto, 2012) using the DRAI reported that Asian Americans and European Americans differently self-reported the expressivity and modification of their emotional expressions. Asian Americans endorsed the expression of their emotions less than European Americans, but endorsed the modification of their expressions more. However, perceived relationship commitment mediated the ethnic group variations on endorsed expressivity. European Americans had significantly higher scores on perceived relationship commitment than did Asian Americans toward parents, close friends, and older siblings, and these differences completely mediated the ethnic differences in display rules. This empirical evidence on the DRAI indicated that culture matters in displaying certain emotions in particular social contexts. Thus, being aware of and understanding cultural variations in displaying emotions in social contexts is important for better social communication and relationships.

Culturally Adapted Psychotherapy

Wei-Chin Hwang

Claremont McKenna College

Culturally adapted psychotherapy refers to the tailoring and modification of mental health services for people of diverse backgrounds. It refers to the larger umbrella term of culturally adapted treatments, which includes the adaptation of both health and mental health services. Although these terms can also apply to other aspects of diversity (e.g. age, gender, sexual orientation, immigration, acculturation, and specific clinical or comorbid issues), the term generally refers to the adaptation of services for different ethnic groups. There are number of terms that refer or are related to culturally adapted treatments, including cultural modifications, cultural tailoring, cultural attunement, cultural competency, culturally sensitive treatments, and culture-specific therapies. Culturally adapting treatments are especially important because access, utilization, and disparities in the prevalence and outcomes of mental health treatment tend to be worse among different ethnocultural groups.

The culturally adapted psychotherapy evolved after the cultural competency movement, which highlighted the importance of being competent and effective when working with different ethnocultural groups. Cultural competency has been defined as consisting of three components: (1) cultural self-awareness, (2) knowledge of other groups, and (3) possessing the skills to effectively deliver services to ethnically and culturally diverse clientele (Sue, 1982). Although many cultural competency practice guidelines have been developed, they tend to be aspirational in nature and focus on general recommendations, leaving clinicians yearning for more practical and concrete advice when working with diverse groups. Culturally adapted psychotherapy may be one such resource for providing additional insight on how to make concrete clinical modifications to the therapy process.

The cultural adaptation movement has largely focused on culturally modifying and testing evidence-based treatments with ethnic minorities. This movement attempts to address and improve treatments to address health and mental health disparities. Whether "as-is approaches" are effective and sufficient in fully addressing the needs of diverse populations has been called into question. Moreover, the impracticalities (e.g. prohibitively time consuming, costly, and lead to therapist training difficulties, especially if they are based on different treatment models) of developing novel ethnic-specific treatments for each culturally

different group in the United States and internationally has been highlighted. Culturally adapting evidence-based treatments (EBTs) are seen as the most practical and cost-effective option to effectively address cultural issues in treatment.

The depth and extent to which cultural adaptation are made can vary. For example, adaptations can be more surface structure in nature (Resnicow et al., 1999) and focus on the modification of more simple and basic elements of treatment, such as providing ethnically matched therapists, conducting therapy in a client's native language, designing clinics to be culturally aesthetic and locating clinics in neighborhoods that are easily accessible. In addition, cultural adaptations can be deep structural adaptations that are more comprehensive and focus on incorporating various elements of culture (e.g. the ideas, beliefs, attitudes, and values) into psychotherapy. Some may consider that surface structure adaptations are not true cultural adaptations (and are merely demographic matching indicators that should only be labeled as such), and that deep structural adaptations are needed in order to truly address and tailor treatment needs for diverse populations. For example, just because a therapist is ethnically and linguistically matched with their client does not mean that they are culturally competent and know how to adapt and tailor psychotherapy to be effective with their clients. Unfortunately, deep structure adaptations are much more difficult to develop, and few frameworks exist for guiding such modifications. Nevertheless, deep structural adaptations have greater potential for increasing client engagement and improving outcomes.

More recently, a number of meta-analyses have shown that cultural adaptations confer additional treatment benefits for ethnic minorities. For example, Griner and Smith (2006) examined 76 studies and found a weighted effect size of .45, indicating that cultural adaptations provided a moderately strong benefit to improving outcomes. Unfortunately, many of these studies did not provide detailed information about how the interventions were developed or adapted. Moreover, 41% of the studies included were ethnic-specific service clinics that provided ethnic matching and linguistic services for diverse clientele. In addition, most studies did not utilize methodologically rigorous design such as randomized controlled trials to test adapted versus non-adapted interventions of the same therapeutic modality. It is possible that if more systematic and deep structure adaptations are implemented, the benefits may have been even greater.

Smith, Domenech Rodríguez, and Bernal (2011) reconducted the previous meta-analysis using refined methodological criteria. Specifically, their meta-analytic review included only studies that used quasi-experimental and experimental designs. Moreover, studies involving only ethnic and language matching were excluded. Some aspect of the content, format, or delivery of the intervention also had to be purposefully modified to address issues of culture, race, or ethnicity. A moderate effect size of .46 was found, indicating that adapted treatments performed better than control groups. However, the definition of control group was still a major problem because nearly all studies utilized wait-list controls, treatment as usual, or compared treatments that were not equivalent in theoretical orientation.

Benish, Quintana, & Wampold (2011) also conducted a meta-analysis to address methodological limitations. Specifically, their study addressed the "file drawer problems" and included both published and unpublished studies. They found that culturally adapted psychotherapy is more effective by an effect size of .32 than unadapted, but bona fide

psychotherapy. However, bona fide psychotherapy did not refer to a cultural adaptation of the same evidence-based practice and theoretical orientation (e.g. culturally adapted CBT versus nonadapted CBT), which again limits the conclusions that can be drawn. Many of the studies also had significant methodological weaknesses and/or biases such as very small sample sizes (e.g. often times with numbers in the single digits or less than 20 participants per treatment condition), providing additional treatment for clients in the culturally adapted arm (resulting in unfair comparisons of lengthier adapted treatments versus shorter nonadapted treatments), conducting therapy in ethnic languages for the adapted condition but English in the nonadapted condition (resulting in participants of differing acculturation levels being treated in each condition), and client-therapist ethnic match biases (utilizing ethnic match in the adapted condition but not in the nondapted condition). These limitations further highlight the need for clinical trials that use more rigorous methodologies and comparability criteria.

Part of the problem is that few deep structurally adapted psychotherapeutic interventions exist, and few studies have utilized randomized head-to-head comparisons of adapted vs unadapted treatments of the same therapeutic modality. Moreover, few guiding frameworks have been developed to help scientist-practitioners develop interventions that incorporate deep structural adaptations. Bernal, Bonilla, and Bellido (1995) developed one of the first frameworks for culturally adapting therapy. Eight different dimensions where adaptations might take place are highlighted, including language, persons, metaphors, content, file concepts, goals, methods, and context when adapting therapy for culturally diverse clientele. This framework has been used to culturally adapt and modify psychotherapy for Latino populations.

Hwang (2006, 2012) developed an integrative bottom-up and top-down framework for adapting therapy for diverse populations, and demonstrated the usage of this model to culturally adapt psychotherapy for Asian heritage populations. The Formative Method for Adapting Psychotherapy Framework (FMAP) is a community-based bottom-up approach for culturally adapting psychotherapy and consists of five phases: (1) generating knowledge and collaborating with stakeholders (2) integrating generated information with theory and empirical and clinical knowledge, (3) reviewing the initial culturally adapted clinical intervention with stakeholders and revising the culturally adapted intervention, (4) testing the culturally adapted intervention, and (5) finalizing the culturally adapted intervention. The FMAP integrates the more theoretically driven and top-down Psychotherapy Adaptation Modification Framework (PAMF) in its second phase.

The PAMF consists of six therapeutic domains and 25 therapeutic principles (Hwang, 2006). The domains include: (1) dynamic issues and cultural complexities, (2) orienting clients to psychotherapy and increasing mental health awareness, (3) understanding cultural beliefs about mental illness, its causes, and what constitutes appropriate treatment, (4) improving the client-therapist relationship, (5) understanding cultural differences in the expression and communication of distress, and (6) addressing cultural issues specific to the population. These frameworks have been used in the first head-to-head randomized controlled trial testing a nonadapted therapy to a culturally adapted intervention of the same therapeutic modality. Specifically, nonadapted CBT was compared to culturally adapted CBT (CA-CBT) for treating depressed Chinese Americans, and found to confer benefits in symptom reduction and reduced dropout (Hwang et al., 2015).

Given that psychotherapy was initially developed for and by White populations, the need to empirically test its efficacy and generalizability to other groups is scientifically recommended. This is especially important given that the majority of the world's population is non-White and comes from non-Western backgrounds. Mental health services around the world tend to be sorely lacking and the notion of psychotherapy and mental health treatment does not exist in many cultures. This unfamiliarity, compounded with the stigma toward mental health services that is highly prevalent among different ethnocultural groups, highlights the importance of effectively engaging and treating diverse populations.

The cultural adaptation of psychotherapy and mental health services, and the ability to understand and address how culture affects psychotherapy process, is critically important. It is also important to note that cultural adaptations are not ethnic or racial adaptations. Specifically, culture is in flux and ever-changing. Therapists who are skilled at culturally adapting treatments must be able to flexibly utilize cultural knowledge to improve services, bridge cultural beliefs with therapeutic concepts, integrate extant cultural strengths, and understand and address cultural issues that may act as barriers or help engage clients in treatment. Although many scientist-practitioners have already begun developing culturally adapted psychotherapies, much more work needs to be done to improve and ensure that mental health services for diverse populations are effective.

In addition, future research also needs to evaluate and test mediators and moderators of change. For example, it may be that level of acculturation is a moderator of treatment outcomes. Cultural adaptations may be more beneficial for those who are less acculturated than for those who are more acculturated. Benefits may also be moderated by ethnic or English-language fluency, age of immigration, or developmental stage in which one migrates. Finally, empirical tests of the mechanisms of change also need to be conducted. For example, which adaptations drive symptom reduction (e.g. utilization of cultural metaphors, developing bicultural communication skills, or addressing culture-specific issues) and/or help retain clients in therapy (e.g. therapy orientations) also need to be validated through empirical research. Specifically, culturally adapted treatments need to retain therapeutic elements that generalize across populations, but we also need to be able to systematically test which adaptations are helpful and validate the reasons why they are beneficial.

Cultural Intelligence

Kenneth T. Wang[1] and Michael Goh[2]

[1] *Fuller Theological Seminary*
[2] *University of Minnesota*

Conceptualized and Categorized

Cultural intelligence is defined as "an individual's capacity to function and manage effectively in culturally diverse settings" (Ang et al., 2007). This term *cultural intelligence* and CQ was originally developed by Christopher Earley and Soon Ang (Earley & Ang, 2003) to measure and research this construct that is a form of cultural competency. Cultural intelligence emphasizes the ability not only to function effectively but also to bridge cultural differences. Ang and her colleagues conceptualized CQ into four different dimensions that correspond to the depth, breadth, and flexibility of an individual's cultural strategies, knowledge, drive, and skills. Metacognitive CQ is associated with strategies and refers to one's mental capacity to acquire an understanding of cultural knowledge. More specifically, the strategies include planning, awareness, and checking. Cognitive CQ is associated with knowledge about various cultures and cultural differences. Moreover, cognitive CQ includes both general knowledge on cultural issues and specific knowledge about certain cultures. Motivational CQ is associated with drive and refers to one's ability to focus and persist in efforts toward functioning in intercultural situations. This drive includes both intrinsic and extrinsic interests, and self-efficacy for intercultural encounters. Behavioral CQ is associated with skills and refers to one's capacity to behave flexibly to function effectively in cross-cultural interactions. CQ skills include verbal behaviors, nonverbal behaviors, and speech acts. A bi-factor theory of the four-factor CQ model has been supported through meta-analysis (Rockstuhl & Van Dyne, 2018).

 CQ's greatest contribution is advancing our knowledge and understanding of intercultural competence beyond simply describing and explaining cultural differences. In slightly more than 10 years of research, CQ has demonstrated through rigorous study that it is strong measurable psychometric construct with construct, predictive, and incremental validity (Matsumoto & Hwang, 2013). While a large body of scholarship

exists that explains intercultural competence as attitudes and worldviews or traits, CQ argues that focusing on situation-specific capabilities is more proximal to predicting effective intercultural performance (Leung, Ang, & Tan, 2014).

Similarity of CQ with Other Concepts

CQ is a form of cultural competency, which can be measured and enhanced. The concept of CQ is a natural evolution from the relatively well-established notions of intelligence quotient (IQ) and emotional intelligence (EQ). As a form of intelligence, CQ is positioned as an ability rather than personality characteristics, interests, or outcomes. Although CQ has overlapping characteristics with cognitive intelligence and emotional intelligence, CQ focuses on predicting performances in intercultural settings and interactions. CQ has demonstrated incremental validity over these other types of intelligence (Ang, Van Dyne, & Rockstuhl 2015). If intelligence research has established that intelligence is one's ability to adapt to different kinds of environments, therefore, CQ reflects one's ability to adapt to different cultural environments. Rather than a culture-specific skill, CQ is a more general capability that enables negotiation across different cultural environments. CQ is a "state-like individual difference" that is malleable and can be developed through experiences and training.

Measuring CQ

There are three broad types of CQ measures: (a) self-reported measures where participants report their own CQ capabilities; (b) informant-based measures where knowledgeable observers rate the person's CQ capabilities; and (c) performance-based measures where individuals demonstrate their CQ capabilities through standardized tests.

The most commonly used measure of CQ is the Cultural Intelligence Scale (CQS). The CQS was initially developed as a self-report scale, which included 20 items measuring the four-factor CQ model with the dimensions of metacognitive, cognitive, motivational, and behavioral CQ. The factor structure of the CQS has been examined with samples of individuals from multiple countries including Korea, Singapore, Turkey, and the United States of America. With advanced research, the CQS expanded into a 37-item measure that includes 13 subdimensions with more specified areas within the four dimensions. Owing to its self-report nature, the CQS is viewed more as a subjective form of cultural self-efficacy, which has been criticized to be different from one's actual ability to function in cross-cultural settings.

To address the limitations of self-reported CQ, the CQS can also be used as an informant-based measure where another knowledgeable person, such as a peer, supervisor, or observer rates the level of CQ based on the CQS items. This method of assessing CQ attempts to reflect more of the person's CQ reputation. The convergent validity between self-rated and other-rated CQ has been found to be adequate with reasonably high correlations between the two (Ang et al., 2015).

Performance-based CQ measures have been a recent development to assess CQ. This type of measure draws on the situational judgment test paradigm. With a CQ situational judgment test, participants are asked to identify the best course of action in response to

videos of intercultural work-related situations. The CQ situational judgment test has demonstrated the ability to significantly predict task performance and interpersonal citizenship behaviors (Ang et al., 2015).

CQ and Personality

As mentioned previously, CQ is conceptualized as a malleable form of intelligence that can be developed through exposure to different cultural contexts. Therefore, CQ is conceptually different from personality traits. However, CQ is associated with personality traits in that personality traits influence behavioral tendencies and personal experiences that in turn impact the development of CQ. In studies that examined the relationship between CQ and big five personality traits, openness to experience was found to be most strongly related to CQ, and moreover, significantly associated with all four CQ dimensions (Ang et al., 2015). Other big five personality traits were found to be only associated with certain CQ dimensions. For example, extroversion predicted only cognitive, motivational, and behavioral CQ, but not metacognitive CQ. Emotional stability and agreeableness predicted behavioral CQ only, whereas conscientiousness predicted metacognitive CQ only.

In addition to the factors predicting CQ, CQ in turn is also predictive of performance and psychological outcomes in cross-cultural settings. Individuals with higher CQ reported better general, work, interactional, and psychological adjustment. Various dimensions of CQ predicted decision-making ability, task performance, cultural adaptation, cross-cultural interactions, and the development of a stronger social network (Ang et al., 2015).

Mediating Effects of CQ

Not only is CQ associated with personality traits and adjustment outcomes, CQ mediates the relationship between the two (Ang et al., 2015). For example, CQ was found to mediate the effects of cultural empathy, open-mindedness, and flexibility on the adjustment of international students. CQ has also been found to mediate the relationship between openness to experiences and job performance of expatriates. In addition, the relationship between prior international experiences and adjustment outcomes has also been linked through CQ. In sum, CQ is a critical factor explaining why personality traits and prior international experiences are related to more positive and adaptive cross-cultural adjustment and performances.

CQ has also been found to serve as moderators that affect the relationship between certain variables (Ang et al., 2015). For example, for leaders with higher levels of CQ, the effectiveness of their transformational leadership and organizational innovation was stronger compared to leaders with lower CQ. In another study, CQ was found to interact with cultural diversity in predicting voice instrumentality. For those with high CQ, the relationship between cultural diversity and voice instrumentality was positive; in contrast, for those with low CQ, the relationship between these two variables were negative. Therefore, there are certain positive effects between variables that only exist among those with higher levels of CQ.

Enhancing CQ

CQ is malleable and can be enhanced through life experiences as well as training. Having cross-cultural experiences has been found to be a key in enhancing CQ. Moreover, individuals who spend more time and interact with culturally different locals overseas have been found to have the steepest increase in CQ. Not all individuals develop CQ at the same pace. In a study with Chinese international students, four different patterns of CQ development trajectories were found during their first semester of studying abroad (Wang, Heppner, Wang, & Zhu, 2015). There were groups with (a) consistently high CQ scores, (b) decreasing CQ scores, (c) increasing CQ scores, and (d) a sharp decrease in CQ scores over the first two months, which later rebounded at the third month.

Although CQ can be developed through experiences abroad, specific factors that facilitated CQ development included the processes of resolving cultural dilemmas, developing a new worldview, and making sense of the emotions experienced. Therefore, it is not simply the cross-cultural experiences that enhance CQ but rather a sequence of interactive learning where CQ develops. Experiential learning theory suggests that CQ is enhanced through a learning cycle of (1) engaging in direct cross-cultural experiences, (2) critically reflecting on the experiences, (3) abstracting these reflections into general concepts that guide future behaviors, and (4) actively experimenting with the new behaviors and to assess their effectiveness.

Systematic programs have been designed using experiential learning and social contact principles, which have shown a positive impact on the development of CQ. However, there were differences in the growth trajectories of the different CQ dimensions. For example, participating in a four-week virtual multicultural working teams with members from five different countries resulted in a significant increase in metacognitive, motivational, and behavioral CQ, but not cognitive CQ. Perhaps the cross-cultural interactions provided participants a better realization of their limited cultural knowledge. In contrast, training programs that emphasized lectures have been found less effective. These types of programs resulted in decreases in cognitive and metacognitive CQ. A possible explanation is that the sessions made trainees realize their limited intercultural competence without offering them actual experiential opportunities to enhance their CQ. Overall, programs with higher quality intercultural contact led to greater increases in CQ (Ang et al., 2015).

Ang and Van Dyne (2008) edited a seminal handbook that represented the fast-growing breadth of CQ across disciplines of study. Twenty-four conceptual and empirical papers reflected the theoretical rigor, psychometric qualities, and nomological network of this concept, the specific role of CQ in multicultural teams, as well as the versatility of CQ for application in such fields as applied linguistics, counseling psychology, and short-term missionary work. Additionally, it has been proposed that CQ presents a framework for teaching that helps with bridging the relationship gap between teachers and students as well as developing students' skills that engender global, citizenship, and character education (Goh, 2012).

Personality and Prejudice

James M. Jones and Eric D. Splan

University of Delaware

Intellectual and Social Context

In his classic book, *The Nature of Prejudice,* Gordon Allport (1954) observed that "One of the facts of which we are most certain is that people who reject one outgroup will tend to reject other outgroups. If a person is anti-Jewish, he is likely to be anti-Catholic, anti-Negro, anti-any outgroup ... Prejudice is basically a *trait of personality*" (pp. 68, 73). Prejudice was generally perceived as a flawed personality, a trait that distinguished a person from the norm, a kind of deviancy or psychopathology.

Prejudice, in this early view, was an irrational mental process that permitted individuals to persist in a negative attitude toward outgroup individuals for which confirmatory social information did not exist or precluded their ability to evaluate properly the information that was available. The net effect was a dysfunctional syndrome of hatred, negative affect, stereotyping, and the variety of behaviors to which these psychological states give rise.

The focus on prejudice grew as social scientists addressed the problem of *de facto* and *de jure* racial segregation and discrimination. LaPiere (1934) traveled across the United States with an Asian couple and found accommodations everywhere they went, even though a follow-up letter to the establishments asking if they would allow Asians to stay were uniformly answered No! Prejudice was definitely a personal characteristic, but it also was characteristic of societal attitudes, policies, laws, and conventions.

Through increasingly sophisticated theorizing and research methods, the concept of prejudice evolved from mainly a negative personal attitude toward members of an outgroup based on stereotypes about the group, to outward expression of underlying feelings, often unconscious, that reflect fundamental mental and emotional psychological processes. Prejudice is not entirely irrational or pathological, but a product of human psychology.

The social context of intergroup relations shifted dramatically from 1954, when Allport's book was published and the *Brown v. Board of Education* decision declared racial segregation unjust and illegal, through the 1970s. The broad social eruptions produced by the civil rights and women's movement, the Disability Act and later immigration policy and an

aging population and increasingly foreign-born citizens, meant that prejudice was more complicated to identify and understand (see Jones, Dovidio & Vietze, 2014, Chapter 3). Explicit biases signaled by the personality view, were challenged by growing evidence of the subtle, implicit, and mental models of attitudes and behaviors that were associated with prejudiced behavior. While overt expressions of prejudice subsided, subtle expressions persisted.

At the macro level, social norms and customs were no longer excuses for bias, but drivers of it. However, these influences were related to interiorized thoughts that, while below awareness, were shown to determine prejudiced behavior. The challenge was to understand those individual variations in biased thought and behavior – the prejudiced personality indicated by greater susceptibility to negative norms and beliefs – while also recognizing that in varying degrees, everyone was susceptible to a variety of prejudicial biases. The research and theorizing about prejudice articulated a more mainstream view of its normalcy rather than its abnormality.

Changes Over Time

Allport describes certain cognitive and attitudinal dispositions that are common among individuals who are prone to high levels of prejudice. Prejudice-prone individuals, he argued, tend to exhibit strong preferences for social order, a strict adherence to moral conventions, and submission to authoritarian leadership. Further, those prejudice-prone personalities prefer cognitive dichotomizations or "black and white" thinking and exhibit a weak tolerance for ambiguity, instead preferring predictability and certainty (Allport, 1954, pp. 395–408). The *authoritarian personality* emerged as a summation of the traits Allport theorized as the prejudiced personality (Adorno, Frenkel-Brunswik, Levinson, & Sanford, 1950).

The authoritarian personality – marked by rigid thinking, adherence to traditional values, a projection of inner hostility onto others, and an emphasis on the use of force and aggression – was one of the first attempts to identify those with prejudice inclinations. Adorno and colleagues conceived of authoritarian traits as akin to fascism and developed the F-scale, to measure a person's susceptibility to fascist propaganda. While effective in identifying individuals with generalized prejudices, the use of this scale was relatively short-lived due to critiques regarding the scale's validity, particularly its bias in targeting right-wing political stances as fascistic and its sensitivity to response acquiesce. Although Adorno's approach to authoritarian personality fell out of a favor, it spurred the development of more nuanced contemporary trait measures that better capture dimensions of the prejudice-prone personality identified by both Allport and Adorno.

Right-wing authoritarianism (RWA), (Altemeyer, 1981) is a widely cited update to the authoritarian personality. RWA reflects the degree to which an individual adheres to traditional conventions and norms and tends to be submissive to authoritarian leadership. Individuals with right-wing authoritarian personalities also tend to support the use of aggression and force to suppress social forces who threaten their traditional values.

Similar to RWA, social dominance orientation (SDO) (Sidanius & Pratto, 1999) taps into one's need for social order by measuring the degree to which individuals support

hierarchy-based social systems. Those high in SDO tend to support group-based social hierarchies that exacerbate social inequalities by allowing high-status groups to dominate low-status groups. While these two traits are often related to one another, they tap into different dimensions of the prejudice-prone personality. RWA emphasizes support for the adoption of conventional norms and submissiveness to authority, while SDO is associated with a desire for a group-based social hierarchy. Importantly, both traits are associated with the display of explicit prejudice and discrimination

Major Dimensions of Personality and Prejudice

Allport's *trait of personality* has been crystallized as *generalized prejudice*. However generalized prejudice has been qualified by the distinction between devaluing outgroups generally, or groups low in power and status specifically. Research by Bergh, Akrami, Sidanius, & Sibley, 2016) concludes that generalized prejudice results in devaluing marginalized groups. Current research, though, has expanded the specifics of generalized prejudice to include (in addition to authoritarian personality, RWA and SDO) psychological attributes such as psychological inflexibility, perspective taking, and empathic concern. Research shows that these variables predict prejudice level over and above indicators of generalized prejudice (Levin, Luoma, Vilardaga, Lillis, Nobles & Hayes, 2016). Other dimensions emphasize more general cognitive processes such as preference for dichotomy, intolerance of ambiguity, and mindset. A cognitive need for closure (NFC) (Kruglanski, 2004) reflects both a preference for dichotomy and an intolerance of ambiguity. The high NFC person desires situational certainty and predictably and tends to see social groups as more homogenous and less individuated. This tendency subsequently increases the likelihood of using group-based stereotypes to make inferences about individuals or their behaviors which can lead to more prejudiced attitudes. While having trait like dispositional tendencies, NFC has also been found to be sensitive to situational demands such as time pressures.

Additionally, dichotomized social thinking – mindset – indicates an individual's lay theories of human nature. Specifically, beliefs about prejudice, and the degree to which one views dispositions as fixed, have been linked to discriminatory behaviors. The belief that prejudice is a fixed trait has been associated with poor intergroup interactions and a general disinterest in reducing personal prejudices (Carr, Dweck, & Pauker, 2012). However, a malleable mindset, while also measured as a trait, is more sensitive to social contexts and can be situationally altered.

Current Work and Emphasis

These cognitive and attitudinal dimensions of prejudice have been reliably predictive of explicit discriminatory behaviors and prejudiced attitudes; however, they may not be adequate in explaining subtle modern forms of prejudice. Modern prejudices are often not explicit and may at times even be unintentional. Many common forms of modern prejudice come from well-meaning and egalitarian-minded individuals who do not strongly match the prototypical prejudiced personality.

While these dimensions of the prejudice personality appear to play a vital role in leading to discriminatory behaviors, understanding implicit forms of prejudice must be examined in terms of the social, historical, and cultural contexts. This is particularly true for the more contextually malleable dimensions of NFC and fixed mindsets. However, it is also relevant to SDO and RWA, which are motivated by a fear or antagonism directed at outgroups perceived to be socially or economically threatening.

Modern emphasis on prejudice takes on a socio-cultural perspective, which examines the influence of personality in terms of the current social context. One prevailing model that has extended this socio-cultural perspective of prejudice is Mischel and Shoda's (1995) cognitive-affective personality system (CAPS). CAPS stresses the dynamic interplay between personality and the social context in motivating behavior, particularly in the case of inter-race/ethnic interactions. Recent research has emphasized the role of these prejudice-prone personality dimensions within different contexts (outgroup status, situational demands, societal pressures) and the ultimate effect this interaction has on the expression of negative group attitudes (Hodson & Dhont, 2015).

Future Directions in Research, Theory, and Methodology

Current work emphasizes trait-based consistency, psychological variables that interact with these generalized traits, and situational factors that moderate them. The result is complexity of the prejudice concept that drives current theory and research (Hodson & Dhont, 2015). The major future direction should focus on these complex interactions among traits, psychological dispositions, and social contexts in producing prejudiced behavior. Although generalized prejudice asserts a prejudice type, variations in outgroup characteristics have been shown to matter and should be explored further. Another important consideration is the effect of prejudice on its targets. This has been a major focus of prejudice research over the last two decades and is critical to understanding the reciprocal effects of prejudice on actors and targets. Target responses have been described in terms of resilience and self-protection, as well as poor psychological well-being. Determining what factors influence which of these effects will occur, and when, are important theoretical and research goals. Further, more longitudinal investigations are needed to chart the course of interactions over time and discern how reactions of targets affect prejudiced actors and undermines or fortifies intergroup relations. The explosion of work on implicit processes has illuminated factors that have theoretical, empirical, and practical significance. Ultimately, prejudice reduction, a longstanding objective of prejudice research, needs more finely developed theorizing and empirical studies and can itself be a focal point of future research.

Universality vs. Cultural Specificity of Personality

Joshua Thompson, James R. Camp, and Joseph E. Trimble

Western Washington University

Introduction

Emerging as a reaction to social evolutionist theories, the study of culture and personality focuses on the interaction between psychological behaviors and the overarching culture involved. Several approaches have been taken, including biological, humanistic, psychoanalytic, and trait assessments. With the development of more precise, scientific measures of personality the trait perspective quickly came to dominate the field. This perspective relies on the theory that personality traits are innate and dispositional characteristics and can be universally observed across cultures. While this theory still dominates the field, a number of different perspectives have emerged in recent years to challenge the perspective. A culturally situated perspective argues that personality is not simply the result of biology but is, instead, highly influenced by different cultural orientations and child-rearing practices. The conflicting perspectives lead to the debate over whether personality should be considered the result of dispositional traits or whether personality is the result of culturally specific characteristic adaptations influenced by unique lifeways and thoughtways. Other arguments add to this debate by suggesting that personality is the result of both innate dispositions and characteristic adaptations.

Psychological Perspectives of Personality

Personality is often conceptualized as the embodiment of a person's thoughts, feelings, and behavior. Psychology, in the late 1800s, was a relatively new and emerging field influenced by the "exact sciences" of the time; it was eager to offer insight and practical solutions to the questions of personality in a psychometric form.

In the 1920s Gordon Allport opted to ratify "trait" as the key concept for the newly emerging field of personality that had important consequences in framing such later issues as the ways in which personality is measured, stability versus change, the roles of "personality," and "situation" in the explanation of behavior and the relationship between trait and other

personality constructs such as motive (Allport, 1927). Allport identified 4,000 traits that can be identified in the personality of individuals. Despite his in-depth analysis of what traits comprise a personality, Allport's work made it difficult to narrow down and analyze which traits are most persistent and in regard to anthropology and which traits are consistent across cultures.

Many years later, Raymond Cattell (1965) developed an influential but controversial 16-personality factor model in an attempt to create a common taxonomy for personality traits. Using factor analysis as a modeling technique, Cattell described 16 personality traits that were used to explain differences between people's personality. Cattell used three sources of data:

- L Data: life record data such as work/school attendance
- Q Data: questionnaire to rate a person's personality
- T Data: objective tests to "tap" into a personality construct

Henry Murray, a Harvard psychology professor for over 30 years, developed a theory of personality based on the individual's needs. Rooted in Murray's psychoanalytic teachings, he believed that a psychological need is a readiness that responds in a certain way in certain circumstances (Murray, 1938). The theory is based on the notion that there is an internal disequilibrium and the core self lacks and desires something. Needs are categorized into either primary (biologically based, e.g. food, water, shelter) or secondary (derived from biological needs or are inherent in our psychological nature, e.g. achievement, dominance, affiliation).

Murray is better known for the development of the Thematic Appreciation Test (TAT) that is also associated with psychoanalytic principles. The TAT involves giving participants pictures and having them write or describe stories about what they see. The psychologist then determines an individual's needs (derived from Murray's needs theory) based on what they wrote or said.

Throughout the twentieth century, personality psychology was heavily dominated by the study of personality traits. Research was expedited to lie out a common taxonomy for personality traits with an emphasis on the use of universal personality measures. With societal tension brought on by WWI, "mental tests" became popularized in the field to distinguish individual differences in the workplace, military, and schools (Parker, 1991). The tests were trait oriented and offered a quick diagnosis and judgment of a person's character, e.g. introversion vs. extraversion. The test-driven judgments were often misjudged as they focused on Western ideals and values to categorize people's personality. These categories reflected the morals and needs as seen fitting by the scientific elite who were mostly funded by military-focused organizations.

In the late nineteenth century through the mid-twentieth century, personality was understood as something innate and unaffected by the individual's surroundings. Traits later became better understood as dimensions of personality that overlapped with one another. There are several personality theories currently accepted in the field, with the Five Factor Model dominating the perspective. The Five Factor Model uses five dimensions of personality known as OCEAN: Openness to Experience, Conscientiousness, Extraversion, Agreeableness, and Neuroticism. The model is used similarly to Freud's

tactics of measurement where an individual's personality may fall low between one or more dimensions, possibly indicating a psychological abnormality.

Despite its origin in Western science, the Five Factor Model has demonstrated to be a generally accurate personality measurement across cultures.

Cultural Specificity in Personality

Culture and personality became of interest once researchers in anthropology and psycho-analytic theory found interest in each other's work. Various interdisciplinary programs were funded during the 1930s through WWII, but interest was lost during the start of the Cold War with economists and political scientists dominating world issues and circumstances. Owing in large part to their field research in different cultural settings, anthropologists raised questions of whether personality traits were universal in origin. Additionally, the solidification of traits in the field of Western psychology provided a basis for anthropologists to compare personalities across cultures. Increasing globalization in the 1990s called for more influence of culture influences and varying child-rearing practices on personality psychology.

The Five Factor Model uses a lexical approach and has been translated in numerous languages ostensibly for use with various ethno cultural groups. Current studies show systematic patterns across cultures however interpretations of findings vary. The absence of certain dimensions does not necessarily indicate a personality defect but rather that the dimension at hand could be unimportant to that culture. While the dimensions of the Five Factor Model may be present across cultures, it does not detect signs of novel traits that may be unique to a particular culture. The neglect of culturally distinct traits is where the attempt at universalizing personality loses some value. As a result of the inquiries an anthropological perspective appears to be crucial in the understanding of personality.

Research in cross-cultural gender differences in personality also shows universal patterns across cultures. Expectations of personality differences among cultures are often mistaken.

Gender differences in personality are more common in modern European countries than in more traditional societies (e.g. South Korea, Japan, China, etc.). One explanation for this misconception is that a person might attribute a trait as part of their own personality while another person attribute that same trait as part of their role as a man or woman.

A current argument in the study of culture and personality is whether personality is a set of dispositional traits, as argued by trait psychologists, or whether personality consists of what are referred to as characteristic adaptations. The argument for the idea of characteristic adaptations revolves around the belief that traits are not necessarily innate dispositions but, instead, are driven by society, culture, motives, drives, and coping mechanisms. This argument states that while individuals may possess certain innate dispositions, the extent to these are manifest in the individual depends highly on enculturation.

Cultural psychologists, in particular, tend to focus on the "mutually constitutive" nature of culture and personality. Both personality and the self are seen more as social constructs and

therefore vary across cultures. One example concerns the differences in individualistic and collectivist cultures. Within individualistic cultures, members are viewed as being more autonomous. Within this cultural construct, individuals will have distinctive dispositions which can drive behavior. This view allows more for ideas that personality is innate and dispositional. Within in collectivist cultures, the thought of the individual is minimized. People are viewed more as part of the whole. Since this type of culture is more society focused, behavior is often viewed as a response to the group as opposed to dispositional (Church, 2010).

Indigenous psychologists tend to argue that personality as an innate disposition does not take into account culturally specific constructs. Some of these include the Japanese construct of indulgent dependence, the Korean constructs of affection and dignity, and the Mexican construct of the avoidance of conflict. While many of these constructs are taken into account in the Five Factor Model, they may appear to be different within non-Western cultures. Indigenous psychologists are more likely to view personality traits as characteristic adaptations because they view cultural context as salient. They believe that personality traits are the result of universal tendencies and motives and their interactions with specific cultural settings and enculturation.

Anthropology and Personality

American linguist and anthropologist Edward Sapir is considered to be among the first to begin to establish the study of culture and personality as a unique subfield of anthropology. He was heavily influenced by Gestalt principles, particularly the idea that perception can only be understood when considering meaning as a function of organized patterns. He applied this theory to the study of language, culture, and personality. Ruth Benedict expanded on Sapir's work by arguing that culture determined the meaning of its parts and the relationships between them.

Franz Boas's early contributions to culture and personality began with refuting common evolutionist theories that tried to explain cultural differences using the universal human evolution scale. Boas's work emphasized the plasticity of human nature that can be found in any individual allowing them to develop the behaviors elicited by a culture. This characteristic helps to account for the variety of differences seen across social groups. As a student of Boas, Margaret Mead approached the study of culture and personality by examining what she called "dominant cultural configurations." These prominent researchers in the field helped to develop the formal field of psychological anthropology.

A New Model for Studying Culture and Personality

Higgins (2008) believes that in order to accurately study personality across cultures a new model must be developed; to accomplish this goal he proposes a five-step approach. The model relies on the need to take into account universal motives that may underlie both personality and culture. The iterative steps take into account a number of perspectives including evolutionary, social, and cross-cultural. Higgins believes that in order to accurately relate culture and personality, the following criteria must be met:

- Identify universal principles of human functioning that underlie both culture and personality.
- Treat those principles at different levels of analysis for culture and personality.
- Define culture and personality in terms of those principles in a manner that maintains the integrity of these concepts.
- Select specific psychological factors that, because of their survival value, are present in every culture and individual, although to varying degrees.
- Postulate how different cultures and personalities emerge from variability in the predominance of those specific psychological factors.

Higgins also believes that the variability in universal motives could be a missing link in the study of culture and personality. His novel argument is much in line with the idea of personality being the result of characteristic adaptations. While many human motives are universal, the means by which these motives are realized is highly dependent on cultural context. In Western cultures, these motivations are more individualized while in more collectivist cultures they are group dependent. Higgins argues that understanding how culturally specific motives influence the development of personality traits may lead to a more acute process for measuring personality across cultures. In addition, these measures could offer explanations to differences in personality cross-culturally.

Though there are a number of perspectives in the understanding of personality, the majority of theories rely on the idea that personality possesses an innate component. Further understanding of cultural contexts has led to the pursuit of understanding personality on levels beyond concepts of inherent behavior. As Higgins would suggest, perhaps the debate is an incomplete one that requires a shift in focus to examine dispositions in a more cultural context.

Conceptualization of Individualism and Collectivism

Conceptualization of Individualism

Individualism is grounded in the belief that individuals are separate beings with personal differences that make him/her unique from their group (Triandis, 1995). Such individuals have the tendency to describe himself/herself as a person first (e.g. "I") as opposed to a member of a group (e.g. "sister"). This is called an independent view of self. Larger focus is placed on internal processes and desires including goals, values, needs, preferences, rights, and identity. These guide and motivate an individual's behavior and thoughts irrespective of conformity to one's group (i.e. personal goals will override goals of the group). Therefore, individualists behave in accordance with their attitude as opposed to the norms and mentality of their group. *Idiocentric* is another term for individuals or countries that follow the individualist view of self, goals, and behaviors (Triandis, 1995).

Features and components of individualism include autonomy, self-reliance, individual achievement, competition, unrealistic expectations of their relationships (e.g. abandoning personal needs and wants for others), and feelings of insecurity (Berry, Segall, & Kagitcibasi, 1997). Individualists encourage creativity and personal differences, valuing equality of individuals and liberty from others. Therefore, they are inclined to satisfy their own desires and goals over that of others, focusing on action that allows for personal benefit. Individuals also maintain equality through rejection of authority figures and distribution of rewards. In their political and social systems they have been identified to spend large amounts of money on military spending. In particular, American individualists value separation from family, religion, and community (Berry et al., 1997).

Individualists aspire to achieve self-satisfaction, and reach one's full potential (Berry et al., 1997; Triandis, 1995). Consequently, individualists maintain an internal locus of control, assuming personal responsibility for their actions and well-being. In order to attain such goals, individualists deny rigid standards and avoid social pressures of conformity. Hence, it

is likely that individualists maintain looser connections to people in their immediate group and larger society. Relationships with others are evaluated and maintained when considered beneficial to the individual and consistent with his/her beliefs. However, anthropologists have viewed individualists as more accepting of differences in relation to family structure and aesthetics. Furthermore, individualists have more freedom to maintain differing political and religious affiliations (Triandis, 1995).

Literature has identified two types of individualism, horizontal and vertical (Triandis, 1995). Both groups value high freedom, independence, achievement, and an autonomous view of self (i.e. independence). Based on this premise, achievement is determined from one's contributions (e.g. effort) for both groups. In addition, both groups follow market-pricing system, meaning the quality of an individual's contributions establishes the value of the outcome one receives (e.g. money) (Triandis, 1995). Within this system, the self is frequently defined by occupation, which as a result affects their role and profit in society.

However, horizontal and vertical individualists differ in numerous ways. Generally, horizontal individualists value harmony (Berry et al., 1997). More specifically, horizontal individualists maintain the same value of independence, but strive for uniformity among group members, so that no individual stands out from the group. These groups emphasize equality in work and social justice. They prefer to maintain a democratic government and a collectively shared economy, whereby every member contributes to managing the economy.

Alternatively, vertical individualists generally value power distance, highlighting independence from people of power and authority. Emphasis is placed on respect, loyalty, and obedience in relationships (Berry et al., 1997; Triandis, 1995). In contrast to horizontal individualism, they respect individuality from one's group and utilize achievement to acquire a distinct status. The members of this group strive to "be the best" and favor a democratic government with a capitalist style economy (i.e. an economic system operated by private ownership and profit) (Berry et al., 1997; Triandis, 1995). Therefore, one's status equates to fortune and success. Resources are distributed according to rank and inequality is accepted within society (Berry et al., 1997).

Conceptualization of Collectivism

Collectivism is a social pattern that consists of individuals closely interconnected in a group. The collective group determines a person's values, behaviors, needs, norms, and identity. Because collectivists are more likely to identify as a group, they tend to use collective pronouns. The connections between group members exist since birth and are integral in collectivist societies. Each member has specific duties that contribute to the mechanism of interrelated groups and the larger holistic society (Berry et al., 1997; Triandis, 1995). Members adhere to social norms in collectivist societies whereby worldview is shaped by the group's mentality and perspectives of the world. Group members depend on each other for survival, protecting each member and are each devoted and obliged to the group (Berry et al., 1997). Hence, members take into consideration the effect of one's actions on group members. Interaction between group members is more valuable than privacy (Berry et al., 1997; Triandis, 1995).

Features and components of collectivism include the beliefs that the interest of the group is more important than individual interest, individual freedom is dependent on the

group, and social norms are defined by the group and not individual pleasure seeking. Collectivism tends to limit emotionality and creativity in its members. Moreover, collectivist societies value dependence, hierarchy, courtesy, camaraderie, and familial modesty among members of the community. In these communities, collectivistic tendencies emerge from expectations of reward and punishment from the group. In these societies, group achievement is valued beyond individual success. Therefore, the members of collectivist societies tend to have external locus of control and engage in high self-monitoring, such as making sure that their behaviors fit the social norm (Berry et al., 1997). They tend to be cooperative, share their resources, and have attachment to the land. Allocentric is another term for individuals or countries that follow the collectivist view of self, goals, and behaviors (Triandis, 1995).

Collectivist societies value harmonious interactions with others, respect elders, and follow traditions of their ancestors (Berry et al., 1997; Triandis, 1995). Members are focused on group success in contrast to an individual's status. Beliefs of the group members are more likely to be similar to one another and are less likely to set individuals apart from the group. Therefore, an individual's identity incorporates group values and characteristics. Group members are taught to enjoy their specific social roles and make sacrifices to benefit the group. Interpersonally, members are more likely to maintain relations with one's group members regardless personal feelings and attitudes toward them (Berry et al., 1997; Triandis, 1995).

Further examination of collectivist societies also provides two distinctive groups, vertical and horizontal collectivism. Horizontal collectivism assumes complete equality among all members of the group, whereby changes in group rank and equality weaken the camaraderie between members. They do not try to stand out or dominate over other members in the group. The group members' identity, values, behaviors, and status are very similar to each other and differences are minimal. These members commonly live together in a community and share resources equally (Triandis, 1995).

Alternatively, in vertical collectivism each member has a specific duty to fulfill that contributes to the overall benefit of the group. Members in this group are unequal and tend to accept orders from authority figures. Communal resources are distributed in a descending order, starting with a member that has the highest rank in society. Slight deviations from the norms may occur but are not encouraged. Research findings identified most collectivist cultures as vertical (Berry et al., 1997; Triandis, 1995).

Individualism and collectivism also differ in their understanding of ingroup and outgroup members. Ingroup members are similar and show concern for each other's wellbeing. Members maintain a sense of "common faith" causing members to feel intertwined with one another and are impacted by the successes and failures of the group. Examples of ingroup for both individualistic and collectivistic cultures include family and kinship. Outgroup members are dissimilar in their values and attributes. They can also be viewed as harmful or in conflict with the ingroup (Triandis, 1995).

A person belonging to an individualist culture will define their "self" independently from the group (e.g. I am Mary Elizabeth Jones), while a collectivist will define "self" in relation to the ingroup they belong (e.g. I am a mother). However, depending on the culture, groups such as friends, political parties, religious affiliations, language, and locations may function as an ingroup for collectivists but not for individualists (Triandis, 1995).

Individualistic and collectivist cultures are defined by levels of cultural tightness and looseness, as it relates to the degree of agreement on correct action, behavior according to the norms, and criticism for deviation from the norms. Tight cultures have a limited number of correct options when responding to specific situations; individuals are expected to adhere strictly to culture norms. Members receive a punishment if they deviate from norms. In looser cultures, many options are available when responding correctly to situations and provided rewards for independent actions. For example, tight cultures require a couple to be married prior to engaging in a sexual relationship, but individuals from loose cultures have more options (e.g. they can get married or date casually). Tightness generally occurs in homogeneous societies; these societies are often isolated from other cultures. Members usually live in close proximity to one another and praised for following the actions of others. Looseness is associated with heterogeneous cultures, in which people tend to be rewarded for independent actions. Collectivist cultures are usually associated with tightness, and individualistic cultures tend to be looser (Triandis, 1995).

Similarity of Individualism and Collectivism to Other Constructs

Interdependence and independence, despite overlapping with the concept of collectivism and individualism, are not cultural constructs but self-construals. An independent self-construal is embedded in the inherent separateness of individuals. These individuals define oneself by identifying and expressing the uniqueness of self from others. Individuals with independent self-construals view others as reflections to self and as forms of standards of comparisons. In contrast, the interdependent construal views the self as embedded to others and the larger society (Markus & Kitayama, 1991) and view others as representations of the self. Sub-groups within a culture can have different self-construals in a collectivist or individualist society. For example, women tend to have more interdependent self-construals than men even in an individualist culture (e.g. America). In addition, self-construals have direct influence to self-related processes (e.g. cognitive processes and motivational processes) while social constructs do not. For example, individuals with interdependent self-construals will attend closely to information related to people close to them than individuals with independent self-construals.

Explanations of Collectivism and Individualism

There are various explanations for the development of individualism and collectivism. First, the availability of resources impacted the development of collectivism. Living in groups has direct benefits when resources are scarce, increasing the probability of finding food and reducing the probability of harm from outgroup members and external factors. Some examples of these groups include peasant societies, agricultural communities, and family units. However, advantages of living in a group are less obvious when opportunities increased and society becomes more complex and differentiated. Individualist cultures begin to emerge after the shift from hunting and gathering to agriculture and bartering (Triandis, 1995)

Another explanation is the relationship of individualism and collectivism to social class in modern-day society. In countries where economic inequalities are great, people in the

higher social economic class adopt a more individualist culture (e.g. self-expression and leisure) and people in the lower social economic class adopt a more collectivist culture (e.g. dependence on extended family members). Thus, changes in resources, affluence, mobility, economic development and ways people make a living all contribute to a society being either collectivistic or individualistic.

Finally, the size and structure of the family are also related to being more collectivistic or individualistic. A larger family would also require more structure and rules within the family to ensure harmony, which is more closely related to the collectivist culture. The availability of choices tends to be related to individualism, so people who feel more freedom in their choices are generally more individualistic. In particular, women in general have less choice than men in most societies; therefore, they tend to be more collectivistic than men (Triandis, 1995).

Consequences of Collectivism and Individualism

Individual Consequences

Although the consequences of these constructs have not been empirically studied, suggestions have been explored. On an individual level, the consequences of individualism and collectivism include well-being, personality, and social attributions (Triandis, 1995).

In relation to well-being, individuals from a collectivistic background had lower self-esteem, happiness, and life satisfaction compared to individuals from individualistic cultures, including when income was accounted for (Triandis, 1995). Differing expression of emotions including happiness and shame may also contribute to low self-esteem and life satisfaction. For example, East Asian countries attributed low life satisfaction to self-esteem, education, and health.

In relation to life satisfaction and mood, happiness is an emotion more commonly understood and reflected on in individualistic cultures (Triandis, 1995). Collectivistic individuals may not think about their own level of happiness, and instead seek the answer from their close kin. This may also contribute to feelings of low self-esteem or life satisfaction. Triandis (1995) suggested low self-esteem could cause individuals to be at a higher risk for suicide. Specifically, studies showed higher rates of suicide among individuals on the horizontal dimension of either individualism or collectivism. This is because on the horizontal individualists and collectivists do not enjoy standing out from other members of their group, and suicide may offer an escape from feeling shame when they stand out from their members (Triandis, 1995).

Health and Mental Health Consequences

When it comes to health, research indicated differences between members of collectivistic and individualistic societies. For example, studies found that collectivists have fewer heart attacks compared to individualists. However, when individuals from collectivistic societies acculturate to individualistic societies, their rates of heart attacks increased to the level of those from individualistic societies. Also, collectivistic societies provide more

social support during difficult life events than individualist societies. Owing to an increased emphasis of harmony, equality, and social support, members of collectivistic societies are less likely to experience stress than those from individualistic societies (Triandis, 1995). Studies showed that individualists deal with stress by trying to change the environment for personal benefit, while collectivists try to emotionally adapt to the environment and situation (Hofstede, 2001).

Moreover, attitudes toward mental illness differ in collectivistic and individualistic cultures. Individuals with depression from individualist societies report suffering from guilt and the inability to manage stress associated with personal decisions. In collectivistic societies, individuals with depression find the ability to continue functioning because of their social support networks that help them with decision-making. Social support networks in collectivistic societies also play a critical role for patients with schizophrenia; the entire family becomes involved in the treatment. In individualistic cultures, these patients are commonly treated in inpatient hospitals and isolated from their families (Hofstede, 2001). Studies comparing these systems showed patients with psychosis have a better prognosis in collectivistic communities. This improved outcome has been attributed to social support; generally collectivistic cultures offer more social support than individualistic cultures as the main health care practices and treatment for individuals with a mental illness. However, individualistic cultures integrate individuals with disabilities into society more than collectivistic cultures. Furthermore, members of collectivistic societies have relatively lower occurrences of suicide, divorce, and child abuse than members of individualistic societies (Berry et al., 1997).

Personality traits are also influenced by individualism and collectivism (Triandis, 1995). Traits correlated to collectivistists include self-monitoring, social anxiety, and sensitivity to rejection. On the other hand, individualists are unique, less sympathetic, and more self-focused. Members of both individualistic and collectivistic cultures can be high self-monitors, but with differing presentations. Individualistic self-monitors focus on what others desire out of their behaviors, whereas collectivistic self-monitors behave in ways considered more acceptable by their group members (Triandis, 1995). Personality traits consistent with a new culture or country (e.g. an individualist moving to another individualistic culture) may increase the likelihood of the person acculturating to the host-country as they maintain, exhibit, and value the same traits as the host-culture (Triandis, 1995).

Interpersonal Consequences

Consequences of individualism and collectivism also occur on an interpersonal level.

Differences occur in relationships with their ingroup and their social environment. Within their group, notable outcomes appear in social skills, interactions, and conflicts. In their social environment, differences occur in communication and decision-making, self-efficacy, education, love and marriage, and helping behaviors (Triandis, 1995).

In relation to social interactions and social skills, generally collectivists maintain fewer and closer relationships than individualists (Triandis, 1995). Their interactions occur less frequently than individualists, however, their interactions last longer. They tend to view their relationships as more intimate than individualists. Members of a collectivistic culture follow the norms and behaviors of their group and consequently do not develop other social

skills. In addition, they have fewer intimate partners than their individualist counterparts (Triandis, 1995). Individualists, on the other hand, experience more vague and ambiguous social norms in interactions. Owing to their looser and larger number of friendships, individualists develop social skills that appear superficial (Triandis, 1995).

Next, conflict presents itself differently in collectivistic and individualistic individuals and their relationships. Conflict among collectivist individuals aims to try to improve the current situation usually within their ingroup and aims to improve the status of the collective (Triandis, 1995). Common conflicts concern religion, race, language, and economics. On the other hand, alienation is the common conflict in individualistic cultures. From this culture perspective, the goal is to change aspects of society they disapprove of (Triandis, 1995).

Another consequence of collectivism and individualism on society can be seen through communication. When it comes to individualist societies, it is common to communicate via writing. However, in collectivist societies, there is a preference for face-to-face interaction (Triandis, 1995). Furthermore, silence indicates weakness and shyness in individualist communications whereas it indicates strength or disagreement in collectivist communications.

Members of collectivistic and individualistic societies tend to solve problems and make decisions differently. Collectivistic cultures tend to employ a group consensus method, while individualist cultures prefer to follow majority rules and employ individual conflict resolution methods. During conflict, collectivists focus on the history and context. Trust is established through informal negotiations, and a contract usually includes a clause indicating that disagreements should be addressed through consultation. When debating an issue, collectivists tend to use their strongest argument at the end and individualists utilize their strongest argument in the beginning. In the end, collectivists reach decisions through a consensus and focus on the agreed outcome. On the other hand, individualists separate the conflict from history and context. Discussion involves an evaluation of the positive and negative attributes. They pay attention the details of the interactions during the decision-making process and a resolution occurs in the form of a contract (Triandis, 1995).

In social environments, collectivists tend scored higher on self-efficacy and performance when working with their ingroup while individualists reported higher self-efficacy when working alone (Triandis, 1995). In addition, individualists tend to minimize a friend's success to improve perception of their own performance. They are also more likely to avoid responsibilities and give others a larger portion of the work when not observed by others (i.e. social loafing). These findings are less commonly observed among collectivist group members (Triandis, 1995).

There are various teaching approaches within education that can be viewed as a result of individualist or collectivist ideas (Triandis, 1995). In a collectivist approach to education, teachers strictly follow the educational curriculum and utilize strategies that target the group of students' needs as opposed to an individual student's needs. Minimal accommodations are given to individual students and all students are held to the same expectations (i.e. academically gifted or delayed). In this system, students tend to be compared to one another. Furthermore, students learn to take responsibility for the successes and failures of fellow classmates. Research shows that students who were not as capable as others to meet the requirements of the group, had difficulty due to their perceived self-deficiency (Triandis, 1995).

Alternatively, an individualistic approach to education adjusts teaching strategies and work based on individual student needs (Triandis, 1995). Therefore, teachers employ multiple curriculums based on the students' individual and educational needs. In this approach, it is considered acceptable to excel in some areas and not others. Teachers do not hold students to the same standards and teachers conduct performance evaluations on a private and individual basis. Therefore, students do not take responsibility for the performance of other students (Triandis, 1995).

Perceptions and expectation of love and marriage are the result of these construal differences. Collectivists tend to get married prior to feeling in love, experiencing companionship more than passionate love. In marital conflict, collectivists assume a passive role (Triandis, 1995). The expression of emotions during conflict is often withheld and considered a sign of maturity. When seeking help or advice about relationships, collectivists speak with family members and supervisors. Individualists, on the other hand, fall in love prior to getting married, and take an active role in marital conflict. During conflicts, individualists more readily express their emotions. Shared interests and activities are considered important measures of the quality of a relationship. In contrast to collectivists, individualists prefer help from helping professionals, such as counselors or therapists, when in need of relationship advice (Triandis, 1995).

On a societal level, behaviors associated with helping others and social attributions function differently across the dimension of individualism and collectivism. Collectivists view helping others as a moral obligation rather than a choice, even when helping may not be required (Triandis, 1995). Individualists view helping others as a personal choice and may feel less inclined to do so. Differences in social attributions (i.e. one's perception of social situations) also vary based on individualistic and collectivistic cultures. For example, individualists attribute poverty as the individual's responsibility and reflection of their self-reliance. However, collectivists view poverty as a result of the government and social policies, something out of the control of the individual (Triandis, 1995).

Intergroup Consequences

Intergroup relations are affairs that occur between two or more social groups. Consequences of individualism and collectivism on intergroup relations can be observed though acculturation, prejudice, and discrimination and in the workplace. Thus, because collectivists gain their values and social norms from the group, they are more likely than individualists to identify with the intergroup pattern. Identifying individuals in specific groups becomes more clear when members have specific external characteristics, such as facial features or clothing, which differentiate them from other groups (Triandis, 1995).

When it comes to acculturation, collectivists tend to assimilate to a new culture as an entire group while individualists experience individual changes (Triandis, 1995). Research compared the acculturation of immigrants from individualistic and collectivist societies. Findings demonstrated that immigrants moving from collectivistic societies had more difficulty in making friends and experienced negative life events when adapting to an individualist society than immigrants from individualist societies. Similarly, it is harder for immigrants from individualistic societies to assimilate to collectivistic cultures (e.g. an American moving to an African nation would find it harder than an American moving to an Western European nation).

Although adaptation to a new environment is easier when cultural patterns are similar, if members from one's country or family have already moved to the host-country, it is easier for immigrants to successfully integrate into their new culture (Triandis, 1995).

Successful acculturation can be attributed to finding common values shared between individualistic and collectivistic cultures in the new host-culture and country. Understanding education and achievement can help communities to work together to ensure their children are able to integrate into the new society and achieve success. In the new host-culture, if success is considered independent to each member, dissimilar to traditional views of collectivist societies, the collective group still maintains involvement to help each person succeed (Triandis, 1995).

Cultural misunderstandings may occur when individuals from one construct (e.g. collectivist) enter the social structure of the other construct (e.g. individualist), such as employment. For example, if a company comprised of vertical individualists hired a supervisor from a vertical collectivistic society, the supervisor may expect employees to follow his/her orders very closely. However, the employees likely maintain some independence and not follow every order. As a result, the supervisor may view the employees as disobedient while the employees possibly view the supervisor as militaristic and unreasonable (Triandis, 1995).

Intergroup conflict arises when several groups disagree on social standards, which results in prejudice and discrimination of outgroups in a particular society. In collectivistic societies, members identify with a specific cultural group and tend to evaluate others according to the standards of their cultural groups. Members of individualistic societies, especially from societies with upward mobility, dismiss and invalidate members outside of their group in order to gain achievement. Therefore, vertical individualists commonly discriminate more than horizontal individualists. Collectivists discriminate against individuals that reject and neglect the standards of their group (Triandis, 1995).

In relation to corporate culture, there is a reduced need for socialization into the workplace in individualistic societies. Alternatively, in collectivistic societies, there is a greater need for employees to integrate into their work place. Some collectivistic societies provide structured training to socialize new members of the corporate team. Often top officials use slogans and speeches to create a strong sense of identification within the corporate culture. Research indicated higher solidarity among employees provided a better experience and life-work balance in collectivistic societies. Individualist societies do not invest in extensive training to socialize employees to the corporate culture (Triandis, 1995). Instead, they emphasize an individual's abilities, accomplishments, and initiatives.

Societal Consequences

The consequences of individualism and collectivism on societies occur in economic institutions, health, and religion. Collectivistic and individualistic cultures have different economic systems. Individualistic cultures utilize a laissez-faire approach (e.g. capitalism), whereby the government possesses a limited role in the economic sector. These systems employ market capitalism or market socialism, which is based on individualist interests. The market itself is stimulated by competition. These systems also highlight an equal distribution of wealth between sectors. In collectivistic societies, the government has more

control over the economic sector (Triandis, 1995). As a result of governmental involvement in the economic sector, there is a higher likelihood for corruption, power distance, greed, suppression, and poverty in society (Berry et al., 1997). The economy is based on community interests, thus following either state capitalism or state socialism. Therefore, in collectivist societies, one company or a group owns most of the market for a particular product (Hofstede, 2001). Therefore, the market system is dependent on economic monopolies. In addition, there is a greater difference in distribution of wealth between sectors of the economy (Hofstede, 2001).

Also, individualistic societies tend to have higher levels of economic development than collectivistic societies (Berry et al., 1997). One of the founding fathers of economics, Adam Smith, professed that the pursuit of self-interest of individuals, a common goal in individualist societies, would lead to greater wealth among nations. Individualistic societies commonly have a higher degree of wealth in comparison to collectivist societies. One explanation for this difference states that poverty may force members of societies to rely on each other, creating a collectivistic culture. Therefore, with increases in wealth in communities, members have more resources and an increased ability to gain independence from the group (Hofstede, 2001).

Collectivistic societies also have more strictly defined social classes and a weaker middle class, while individualistic societies tend to have greater social mobility and a strong middle class. Research indicated members of individualistic societies as more likely to live in houses with private gardens, have vacation homes, and purchase home and life insurance. Those from collectivistic societies tend to live in apartments and have security from social networks rather than insurance (Hofstede, 2001).

Collectivist and individualist societies also have different religious practices. Collectivistic cultures prefer to worship together in a group. Salvation for members of collectivistic groups is associated with the well-being of their relatives. In most collectivistic societies, there is a single dominant religion and members usually belong to the same religion. Deviations from this religion may separate the individual from the society. Hence, placing individual needs above group needs may be considered evil. In individualist societies, members choose their own path to worship and salvation and accept multiple religions. These societies are considered monotheistic. These cultures worship many divine beings, who maintain extended social networks (Triandis, 1995). These members often use religious practices to attain individual goals. Generally, religious practices in individualist and collectivist cultures tend to reflect values of those communities (Hofstede, 2001).

Utility of the Constructs of Individualism and Collectivism

In summary, individualism and collectivism are useful constructs in understanding the reasons for behaviors and thoughts, which cause and impact societal and cultural differences. Understanding these differences increase one's understanding of political and social conflicts, both past and present. However, these concepts provide an overly simplistic view that generalizes individuals and their behaviors, which does not account for variance within each construct. On an individual level, it is possible for a person to possess traits from both individualism and collectivism, depending on the context (Hofstede, 2001). For example as

Triandis (1995) suggested, "an individual may be very individualistic at work and quite collectivistic in the extended family" (p. 27). Equally, on a societal level it is possible to have attributes consistent with both constructs. This may be a result of an increase in contact between individualists and collectivists. Hence, the placement of countries and individuals on one end of the dimension may not sufficiently encompass universal goals and values (e.g. the world at peace, social justice, preservation of nature) (Berry et al., 1997). Research focused on the combination of the advantageous qualities of individualism and collectivism is called communitarianism (Triandis, 1995).

Personality and Geography

Peter J. Rentfrow

University of Cambridge

Geographical Variation in Personality

For decades, research in the geographical sciences has documented regional variation in political attitudes, educational attainment, social tolerance, and disease death rates. Importantly, research in personality psychology has established robust associations between certain personality traits and political orientation, academic performance, occupational preferences, prejudice, and health. To what extent do regional differences in macro-level outcomes reflect the psychological characteristics of residents?

Research on geographical variation in personality stems from the recognition that various features of the social and physical environment are linked to the ways in which individuals think, feel, and behave. Investigations of geographical variation in personality integrate psychological theories and concepts with different levels of geographic analysis (e.g. nations, states, cities, neighborhoods) by focusing on the spatial distributions of traits and the ways in which they relate to the macro-environment. Research on geographical variation in personality shares some overlap with cross-cultural studies of personality, as both areas focus on associations between personality and the broader environment. But cross-cultural studies typically focus on cultural symbols, practices, and norms whereas geographical comparisons examine issues related to spatial organization (Rentfrow, 2013).

History

Nearly a century ago, social scientists began studying the relations between people and the places in which they live. The focus of the research was to identify the key psychological characteristics that defined and differentiated nations. The studies investigated a range of characteristics, including personality, attitudes, motives, and values. A variety of assessment methods were used, with most studies relying on interviews, observations, and surveys. The information gleaned from the research was thought provoking and controversial, but the findings nevertheless informed psychologists' understanding of culture, group conflict,

economic prosperity, and personality. Ultimately, however, the research had limited impact in psychology and interest in geographical differences faded away (LeVine, 2001).

The early attempts to identify meaningful geographical differences in personality were laudable, but they lacked a robust model for conceptualizing personality and reliable methods for assessing it. So, in the years that followed, personality scientists actively worked to develop an empirically based model for conceptualizing the structure of personality. Eventually, all that work led to the establishment of the Big Five framework, which conceptualizes individual differences in personality in terms of five broad traits: extraversion, agreeableness, conscientiousness, neuroticism, and openness. A number of measures have been developed to assess individual differences in the Big Five, and research indicates that the traits are relatively stable over time and linked to cognition, emotion, and behavior. The establishment of the Big Five framework has led to renewed interest in geographical differences in personality, with researchers returning to the challenge of identifying the key psychological characteristics that define and differentiate nations.

Mapping Geographical Differences in Personality

Currently, geographical comparisons of personality are usually based on self-reports of the Big Five personality traits. Specifically, the self-reports of residents in a region are averaged to produce a mean score for a particular personality trait. This is done for every region so that mean scores for each personality trait are computed for every region represented in the sample. This approach allows researchers to make comparisons of the mean personality traits of residents in different regions. For instance, we might observe that California has a high-mean level of openness based on responses from a sample of California residents compared to the mean levels of openness for other states. In addition to comparing regions in terms of their mean-level personality traits, regional personality data can be merged with secondary data sources to examining associations between the regional psychology and macro-level indicators.

A number of investigations have compared personality traits across nations, states, and counties. National comparisons of personality have revealed differences for each of the Big Five traits. For example, people who live in parts of Asia score low in Extraversion, suggesting they are, on average quiet, reserved, and unassertive compared to residents of other nations. People living in nations in Central and South America score high in openness, suggesting they are curious, creative, and unconventional compared to residents of other nations. People who live in nations in Southern and Eastern Europe score high in neuroticism, suggesting they are anxious, easily upset, and prone to depression (McCrae & Terracciano et al., 2005).

Just as nations differ in personality, so too might regions within nations. Indeed, a number of studies have revealed systematic variance in personality traits across states in the United States, local authorities in Great Britain, and federated states in Russia. Among the Big Five domains, neuroticism and openness show the distinct geographical clustering. In the United States, neuroticism is comparatively high from the Middle-Atlantic regions (New York, Pennsylvania), across the Midwest (Michigan, Ohio), down to the South (Louisiana, Mississippi), and gradually declines westward, with low levels on the West Coast (California, Washington). Openness is high in the more urban and ethnically diverse

areas in New England (Massachusetts), the Middle-Atlantic (New York), and West Coast (California). In Great Britain, neuroticism is high in the East of England and Southwest Wales, and low in Southwest England and Scotland. And openness is high primarily in urban cosmopolitan areas, including London, Brighton, Manchester, and Glasgow.

Links between Geographical Personality and Macro-level Outcomes

Given the evidence that personality is geographically clustered, it is reasonable to consider whether the variation is linked to important macro-level variables. A central aspect of research in this area is to examine the degree to which geographical variation in personality relates to important political, economic, social, and health outcomes. For example, are statewide differences in voting patterns in US presidential elections related to the personality traits of residents? Are regional disparities in health related to psychological well-being? Analyses that address such questions have the potential to shed light on the ways in which personality traits become expressed in behavior and also the ways in which individual characteristics relate to broad social, economic, and political forces.

However, when working with variables that can be measured at multiple levels of analysis (e.g. at the levels of individuals and nations), researchers may assume that findings from one level also apply at another level. But the different levels are logically independent from one another. A failure to recognize this logical disconnection can lead researchers to make incorrect inferences about individuals on the basis of aggregate-level data (i.e. the ecological fallacy) or incorrect inferences about aggregates on the basis of individual-level data. This logical disconnect was famously demonstrated over half a century ago in a classic study by Robinson (1950), where he showed that the ecological (i.e. aggregate-level) correlation between the percentage of foreign-born state residents and the percentage of illiterate state residents was –.53, but that the individual-level correlation between foreign-born status and illiteracy was .12. The ecological fallacy would be committed if one assumed, solely on the basis of the ecological correlation, that foreign-born residents were more literate than native-born residents. Likewise, the individualistic fallacy would be committed if one were to assume, solely on the basis of the individual correlation, that regions with large foreign-born populations have low literacy rates. Thus, associations between aggregate-level personality (e.g. conscientiousness) and macro-level behaviors (full-time employment status) do not necessarily mean that individuals who possess a trait are more likely to engage in that behavior.

Several studies have investigated associations between aggregate personality traits and various political, economic, social, and health indicators. Results from these studies show that mean-level openness is positively associated with liberal political orientation, innovation, and cultural diversity. These associations generalize across analyses of nations, US states, and British local authorities. There is also evidence from studies in the US and Great Britain that economic prosperity is related to the prevalence of individuals with an entrepreneurial psychological profile (defined by high openness, conscientiousness, and extraversion, and low neuroticism and agreeableness) in the region. There is also evidence from analyses of personality variation across districts of London that there are comparatively large proportions of people high in openness living in more ethnically and culturally diverse parts of London. Taken together, results from research in this area suggest that

regions high in openness have large proportions of individuals who actively support liberal political causes, and are tolerant of social, ethnic, and religious diversity.

Many studies have also established robust associations between regional psychological characteristics and various health indicators. Analyses of American states and British local authorities indicate that in areas with high levels of neuroticism, residents have shorter life expectancies and are at greater risk of developing serious illnesses and diseases compared to residents of areas where neuroticism is low. Moreover, analyses of nations, and American states, counties, and cities have revealed positive relationships between subjective well-being and physical health. Overall, research in this area suggests that the psychological health of a population is directly linked to physical health and longevity.

Causes of Geographical Variation in Personality

What are the mechanisms responsible for geographical variation in personality? Research in the area has identified three key mechanisms behind the regional clustering. One mechanism is social influence. The idea behind social influence is that the actions of people within the local environment have an impact on the ways in which other people think, feel, and behave. Numerous studies in social and cultural psychology have shown how social norms encourage certain types of behavior, which can lead individuals to internalize the norms and behave in certain ways. There is also evidence from research on social networks and inter-group relations showing that emotions spread through social networks, such that individuals "catch" the emotions of the people they are around. Thus, social influence contributes to regional variation in personality through norms, institutions, and contagion.

Another mechanism responsible for geographical variation in personality is ecological influence. The idea behind ecological influence is that cognitions, emotions, and behaviors are influenced by features of the physical environment, such as climate, terrain, green space, and urban crowding. Recent evidence suggests that living near open green spaces, like parks or nature preserves, enhances feelings of well-being and reduces stress. A growing body of research on pathogen prevalence and personality indicates that in regions with long histories of disease causing pathogens, individuals adapted to the health risks by developing more cautious and risk-averse traits, such as low extraversion, high conscientiousness, and low openness. Furthermore, large-scale national studies indicate that people who live in parts of the world with demanding climates and few natural resources adopted more communal and collectivistic values in an effort to survive the harsh living conditions.

The third mechanism that contributes to geographical variation in personality is selective migration. Whereas the other two mechanisms emphasize the role external forces play in shaping individuals, selective migration focuses on the active role individuals play in choosing environments. The assumption behind selective migration is that people choose to live in places that satisfy their needs. A number of studies have focused on the personality traits associated with residential migration. The results from those studies suggest that people high in openness and extraversion are drawn to culturally diverse urban environments compared to individuals low on those traits. And people high in agreeableness tend to be drawn to areas whether they have family and friends. There is also evidence that people choose to live in neighborhoods where residents are believed to share the political

views. Taken together, these studies suggest that psychological characteristics influence the decisions people make about where to live, which, at the level of populations, could contribute to geographical clustering of personality.

Introduction

Similar to many other cultures, people living in Japan have long been contemplating and accumulating various ideas about the human mind and personality. When Japan opened the gate of the country to the world in the Meiji Period (1868–1912), knowledge of modern psychology came to be accepted and the psychological view of personality also became popular. Over the next 100 years, various pieces of knowledge of personality psychology have come into and been spread throughout Japan. At the same time, some Japanese personality psychologists have created original theories and generated considerable researches regarding personality psychology. Personality psychology holds an important position in the study of psychology in contemporary Japan. This section will review briefly the history of Japanese personality psychology and reflect on review its present status and the future directions.

Japanese Words of Personality

The two words, *sei-kaku* (性格) and *jin-kaku* (人格), are representative of meaning personality in Japanese. They are Japan-made Chinese words, which were created as equivalent words in translation for personality in English and German when Western culture came into Japan during the Meiji Period. The "*sei*" in *sei-kaku* means nature of human beings, "*jin*" in *jin-kaku* represents person, and "*kaku*" indicates its level and grade. The *jin-kaku* is often used as an equivalent for the English word "personality" and the *sei-kaku* is for the English "character." However, the *jin-kaku* has an evaluative meaning similar to "man of personality" in English and creates some confusion regarding the usage of the words. Therefore, the English word "personality" is often used as it is in

psychology in contemporary Japan. There are also some other words regarding the meaning of personality. *Ko-sei* (個性) means individuality, and *kojin-sa* (個人差) represents individual differences. The word *hito-gara* (人柄) dates from earlier times than the other words explained in this section; *hito* means person and *gara* indicates its texture. The word *ki-situ* (気質) is an equivalent of the English word "temperature"; means spirit and *situ* represents quality.

History of Personality Psychology in Japan

Original personality theories have existed in Japan since the feudal era. Two books written in the sixteenth century, *Jinkokuki* and *Koyo Gunkan*, have dealt with the topic of personality. The former focused on different personalities and the value systems of people living in different providences, whereas the latter focused on the personality types of Samurai.

Yuzero Motora (1858–1912), the first modern psychologist in Japan, earned his PhD degree at the Johns Hopkins University. While studying psychophysics under the supervision of G. S. Hall, he coauthored an article in the inaugural issue of *American Journal of Psychology* (Hall & Motora, 1887). After returning to Japan, he became the first individual to be appointed Professor of Psychology at the Imperial University (now the University of Tokyo) (Sato, 2005). He demonstrated the important role of personality in the study of psychology by discussing it in many of his books. Later, Motora's many distinguished students developed the concept of personality further and established it among Japanese psychologists and educationalists. For example, Tohru Watanabe (1883–1957) published the first book in the field titled *Personality* in 1912 and also translated Stern's *Personology* into Japanese in 1931.

Clinical and abnormal psychology evolved further in the 1920s. Masatake Morita (1874–1938), a famous Japanese psychiatric practitioner, developed a unique approach for the treatment of neurosis that became to be known as Morita therapy. He hypothesized that there was a specific personality type of neurosis, which is similar to Kretschmer's schizophrenic type of personality (Sato, 2007). Yuzaburo Uchida (1894–1966) modified the Kraepelin Mental Addition Test and developed the Uchida-Kraepelin Psychodiagnostic Test, which has been the most widely administered test in Japan for measuring working ability. In 1927, the Ministry of Education issued a directive stressing the importance of "respect for individuality." Soon after the directive, the number of books with the word "personality" and/or "individuality" in the title increased. However, it decreased again in the late 1930s after an ultra-nationalist regime came to power in Japan.

After World War II ended, the US occupying forces gave instructions for the introduction of a more scientific and democratic education system in Japan, and educational psychology became a core subject of teacher-training courses. The topic of personality and adaptation was regarded as one of the fundamental disciplines of educational psychology taught in these courses. Moreover, new concepts such as counseling and educational measurement were introduced from the United States, along with a wide variety of psychological tests, including the Minnesota Multiphasic Personality Inventory (MMPI) and WAIS.

In the 1970s, the blood-type typology of human character became popular in Japan. This theory was developed initially by Takeji Furukawa (1891–1940), a pedagogist and psychologist, but it was psychologically refuted before World War II. Masahiko Nomi (1925–1981), a popular writer, revived this idea and wrote popular books about this typology. Many

Japanese psychologists worked to reduce the prevalence of this typology with their own theories and newly obtained data. Such a response increased the appeal and presence of Japanese personality psychology to the general public.

In 1992, the Japanese Society of Personality Psychology (JSPP) was established and Professor Taketoshi Takuma (1927–2018) became the first president of the association. Since then, the JSPP has promoted the development of personality research in Japan by publishing *The Japanese Journal of Personality* and organizing annual meetings.

Current Status of Japanese Personality Psychology

Personality psychology in Japan has mainly been influenced by US personality psychology. This influence is exemplified by its time-honored emphasis on conducting scientific research and applying the findings from such research to address important issues throughout society. Such an approach has resulted in the emergence of personality psychology as one of Japan's major research fields of psychology (Sato & Fumino, 2005). The Japanese Union of Psychological Associations has 53 academic societies representing different fields of psychology. With approximately 950 members, the JSPP is smaller than the Association of Japanese Clinical Psychology (about 28,000 members), the Japanese Psychological Association (about 7,700 members), the Japanese Association of Educational Psychology (about 6,400 members), and the Japan Society of Developmental Psychology (about 4,200 members). However, for its relative size, personality psychology is an integral part of psychological studies in Japan.

The flagship journal of the JSPP, *The Japanese Journal of Personality*, was first published in 1993, and it contains approximately 30 research articles every year. The annual meeting of the JSPP tends to feature more than 100 research presentations. In support of its growing presence, other journals and meetings also include a plethora of studies regarding the study of personality psychology.

In one year from 2016 to 2017, there were 107 articles in *The Japanese Journal of Psychology* and *The Japanese Journal of Educational Psychology*, which are major Japanese psychological journals. Of these 107 articles, 51 articles (46.7%) contained constructs and assessment of personality traits, and this publishing trend tends to increase every year Watanabe (2018). There were 657 research presentations at the 58th Meeting of the Japanese Association of Educational Psychology, which was held in 2016, and 237 (36.1%) of them were related to the study of personality psychology Watanabe, Y. (2018). Another emerging trend is for articles written by Japanese personality psychologists to be frequently published in many international psychological journals.

Education and Personality Psychology in Japan

Psychological knowledge is taught in high school throughout Japan. This curriculum contains personality-related knowledge on such topics as frustration, defense mechanisms, Spranger's typology of value attitudes, and Maslow's hierarchy of needs, and these subjects, along with other related topics, are also included in the coverage of college entrance examinations.

More than 200 universities and colleges offer courses of psychology, and most of them include classes in personality psychology. Some of the classes are taught by personality psychologists; on the other hand, there are also personality classes taught by social psychologists, educational psychologists, and clinical psychologists. Certification is conferred by the Japanese Psychological Association after completing a curriculum of psychology courses, including one on personality psychology.

A national qualification to become a licensed psychologist authorized by the Japanese government, was initiated in 2018. A principal requirement for this qualification is to complete a master's program in psychology, which includes completing a course on Psychology of Emotion and Personality. The training program for becoming a clinical psychotherapist, which is accredited by Association of Japanese Clinical Psychology, also requires completing a course on personality psychology.

Knowledge of personality psychology is often taught in educational psychology courses as part of teacher-training programs and separate liberal arts courses. There psychology courses, including personality psychology, in the training programs in medical welfare, such as those for individuals training to become nurses, psychiatric social workers, and care workers.

Research Topics and Future Directions

Aoki (1971) conducted pioneering work using the lexical and factorial approach to explore personality structure in Japanese. Following this research, personality researchers found a Big Five component in the Japanese Five Factor Personality Questionnaire (FFPQ Research Group 1998; Murakami, 2003), constructed original Japanese Big Five scales (cf. Murakami & Murakami, 1999; Wada, 1996), and translated into Japanese Big Five scales developed in other countries (cf. Oshio, Abe, & Cutrone, 2012; Shimonaka, Nakazato, Gondo, & Takayama, 1998). The Big Five personality structure is broadly accepted in the contemporary study of personality psychology throughout Japan.

From the early 2000s, the positive psychology movement had also been widespread in Japan as an extension of personality psychology, resulting in the development of considerable research and numerous published articles on such topics as resilience, well-being, happiness, and quality of life. Recently, some economists and educational practitioners also have focused on noncognitive skills relating to personality traits such as grit, self-control, and conscientiousness, which are garnering increased public attention in Japan. Alternatively, other researchers are also interested in dark personality components such as the Dark Triad (narcissism, psychopathy, and Machiavellianism).

Personality psychology in Japan is now a developing field in academia. To continue this trend, it will require Japanese personality psychologists to participate in international collaborative studies. It will also be necessary for personality psychologists to collaborate not only with other psychologists, but also with researchers in other related disciplines such as neuroscience, medical science, epidemiology, pedagogy, economics, and political science.

Personality Psychology in Africa

Elias Mpofu

University of North Texas and University of Johannesburg

Introduction

The notion of personality as a psychological attribute of an individual is widely endorsed as a universal human quality (McCrae, & Costa, 1997). People seem to have consistencies in their self-presentation which mark them as different from others, even within circumscribed cultural settings. With this understanding, personality would be a quality intrinsic to the person and likely unchangeable, but influenced in its expression by context or setting. However, only three of the Big Five personality factors were transportable across language groups (De Raad, Barelds, Mlačić, B., Church, Katigbak, Ostendorf, Hřebíčková, Di Blas, & Szirmák, 2012), suggesting a need for caution in assuming personality to carry the same meaning across cultures. What is of continuing interest to cultural studies on personality is to define the core qualities of personality and the specific ways it is understood and appreciated by members of different cultural communities (Schwartz, Zamboanga, & Weisskirch, 2008; van der Merwe, Ntinda & Mpofu, 2015). In African culture heritage communities (with the caveat that there would be subcultures allowing for different shades of understanding), personhood (way of being) likely is the way personality is understood and appropriated. African cultural heritage settings are diverse in their geographical location to include people of African ancestry on mainland Africa and the diaspora. They also are diverse in cultural expression while with a shared underlying ancestral value system rooted relational personhood or in which a person is mutually actualized in social participation with others.

Personality in Personhood

Personhood in African heritage culture settings is an expressive quality of being which is defined by social awareness and responsiveness in the context of mutual interdependency with others (Simões, & Alberto, 2015). This relationship-oriented conception of personhood is valued in collectivistic culture settings (Mpofu, Ntinda, & Oakland, 2012; Serpell, 2011).

Personhood is a broader concept and inclusive of personality and essentially learned, allowing for functional understanding of how to be a person and with what cultural instruments. It is a "thinking-on-your-feet" person ability quality acquired through deep cultural immersion or lived enculturation by and with community others. A person acquires personhood over time sub-serving intrinsic psycho-behavioral qualities (personality) to relational being affordances such as common good.

In the sub-Saharan African cultural community setting, the pan-cultural concept of *ubuntu* (personhood) stands for grounded learning and enactment of socially primed personal assets for collective welfare. For instance, one has *ubuntu* to the extent that he or she in meeting own personal needs is also sensitive to those of socially networked others (Letseka, 2012). As an aspect of *ubuntu*, personality is only an aspect of personhood and less determining of what a person does or how a person understands the him or herself. Thus, in African cultural heritages, personality cannot fail an individual or be singularly blamed for social outcomes. Rather, gaps in personhood development or lapses in personhood-centric behaviors explain person failures. Conversely superior personhood qualities explain constructive personality for the common good.

Personality in Person Styles

In African cultural heritage settings, to know a person well is to understand his or her temperament and social preferences. From that cultural perspective, the prioritization of preference choices is through pathways to relational being-ness with others based on both natural inclination (personality) and social learning. In other words, temperament styles are in fact person styles giving expression to whom or what a person is.

Temperament styles with evidence in African heritage settings are the four bipolar traits: extroversion (E) or introversion (I), practical (P) or imaginative (M), thinking (T) or feeling (F), and organized (O) or flexible (L) styles (Mpofu, Oakland, & Gwirayi, 2010). These four bipolar styles are defined as follows: extroversion-introversion (where we prefer to obtain energy), practical-imaginative (how we prefer to process and retain information), thinking-feeling (on what we prefer to make decisions), and organized-flexible (when we prefer to make decisions). In cross-section of studies of African countries, teenagers expressed a preference for introverted, organized, practical, and thinking person styles than contrasting styles (Africa Scholarship Development Enterprize; ASDE, 2014; Mpofu et al., 2009).

Spiritual Personality

In African cultural heritage settings, an additional bipolar style appears applicable: spiritual-hedonistic (where we prefer to ascribe our metaphysical or social outcomes) (ASDE, 2014; Silva, & Laher, 2012). For example, Botswana teenagers preferred a spiritual rather than hedonistic person style from the high importance ascribed to spiritual life in that cultural setting.

Nsamenang (2006) described three levels in the evolution of spiritual-social self among African cultural community members to encompass spiritual selfhood, social-experiential selfhood, and ancestral selfhood. Spiritual selfhood is believed to originate at conception or perhaps even before conception as in the reincarnation of an ancestral spirit

at conception. A significant milestone in the evolution of spiritual selfhood is when a newborn is ceremoniously welcomed into the family and community and given a name, which might be of a significant spiritual other in the family (e.g. a departed ancestor). Social or experiential selfhood is acquired from relational learning with community others. Ancestral selfhood is omnipresent in the affairs of the living influencing their choices in enacting personhood (Eze, 2015). At the person level, one's ancestral selfhood begins with biological death and may be continued with reincarnation (Eze, 2015; Nsamenang, 2006). Thus, ancestors as the "living-dead" can potentiate personality and person styles for optimal lived personhood in the cultural community.

Individual Differences

In African cultural heritage settings, personhood qualities are aspirational so that people vary in the extent to which they adopt and translate personhood values to guide their individual conduct. This would explain the diversity of person qualities among members of the same cultural collective in their personal-stylistic qualities. van der Merwe et al.(2015) propositioned that individual differences in expressive personality are also explained by personal modernity or the extent to which individuals identify with global rather than traditionalist culture. As a matter of fact, African community member personhood is likely to be adaptive and selecting attributes to optimize personal functioning in both traditionalist and global culture.

Current Research Approaches

One window to understanding cultural personhood in African culture heritage settings is through their language for constructing notions of personality (Silva & Laher 2012). Consequently, lexical approaches are increasingly used for unravelling the content and structure of personality in African cultural heritage settings (Fetvadjiev, Meiring, van de Vijver, Nel, & Hill, 2015; Hill, Nel, van der Vijver, Meiring, Valchev, Adams, & de Bruin, 2013).

A lexical approach to studying psychosocial phenomena is premised on the assumption that cultural community member understandings are embedded in the semantic meaning of specific language communities (Cheung, Van de Vijver, & Leong, 2011). For example, Nel, Valchev, Rothmann, Van de Vijver, Meiring, & De Bruin (2012), Hill et al. (2013) and Valchev, Nel, Rothmann, van de Vijver, Meiring, & De Bruin, 2013) carried out lexical studies of personality among 11 South African indigenous language groupings (Nguni, Tswana, Sotho Zulu, etc.) to construct the content and structure of personality from the perspective of the cultural community members (n >6735). They utilized semi-structured interviews in which they asked each participant to describe his/her own personality as a sibling, parent, other family relation best friend or other acquaintance would. They concluded from the data that the language culture communities understood personality structure to be defined by nine personality clusters: emotional stability, extraversion, facilitating, conscientiousness, integrity, intellect, openness, relationship harmony, and soft-heartedness. Conscientiousness was defined by a continuum of attributes in personal orientation to achievement (upper-end), dedication, orderliness, self-discipline,

thoughtlessness. Emotional stability was represented on a continuum of attributes from having emotional balance through neuroticism. The extraversion cluster included a range of attributes of assertiveness from dominance to sociality, the facilitating cluster from guidance to encouraging others, the relationship harmony cluster from approachability to meddlesomeness, and the soft-heartedness cluster from empathy to hostility. The personality clusters of integrity, intellect, and openness did not define in attributes on a continuum. Integrity was defined by moral consciousness and fairness, Intellect by attributes of mental discernment from appreciation of aesthetics to social intellect. Quite clearly, relational being is well represented in at least five of the nine constructions of personality (facilitating, integrity, openness, relationship harmony, and soft-heartedness) as understood by native Africans.

Future Directions

The nine-factor characterization of structure of personality among African cultural heritage communities and the content that defines personality attributes goes beyond the Big Five (or Big Seven factor) models reported from Western studies of personality. Of particular significance is that the content that defined a similar-label personality factor in Western cultural settings is different in the African cultural heritage settings of study, and aligned to personology as enacted personality within a cultural setting. Future studies could examine high frequency endorsement of specific personhood attributes to define the salience of the specific person qualities in a cultural setting. Person style also appears to be a broadly serviceable construct in understanding personality in African cultural heritage settings, and studies are needed to map expressive personality over the life span. Specifically, evidence is needed on evolution of these person style preferences over the life span in African cultural heritage settings. Such evidence would add to an understanding of how personality expression through person styles changes over time in the context of personal, collective, and spiritual learning (see also Soto, John, Gosling, & Porter, 2011; Edwards et al., 2014).

The conceptualization personality as an aspect of personhood is likely to be widely shared by African heritage cultural communities whereas the specific indicators are likely to be culturally nuanced.

Personality Psychology in China

Mingjie Zhou and Jianxin Zhang

Institute of Psychology, Chinese Academy of Sciences

The Sage and Junzi Characteristics

In ancient China, there was no such term as *personality*. However, the concept of "character of a person" has been popular among both scholars and ordinary people. In Chinese traditional culture, "character of person" signified two things: first, it indicates the unique characteristics of a human being. It is the character that differentiates human individuals from animals; second, it emphasizes moral values that human individuals should follow when interacting with others in families and societies. The most-valued Confucian character is that of a Sage. A Sage's character must manifest the morals of "benevolence," must hold the principles of "being Sage inside and being kingly outside," and must cultivate the thinking habits of introspecting oneself every day. All of them would produce a perfect and complete personality, and be an ideal example of good character for the Chinese to survive well in the culture.

Of course, this ideal character of Sage could not be easily cultivated for the common people. Therefore, Confucianism designed another more accessible standard to be a person with good character, which was called *Junzi*. According to Confucius, Junzi possesses attributes of "compatibility and harmony" (according to Dainian Zhang), which enable them to deal with various relationships, such as those between heaven and human beings, self and others, mind and body, etc. In fact, the character of Junzi should not only behave in the manners of benevolence, love, equality, respect and mercy, but also should have characteristics that promote mutuality, interdependency, and harmonious development interpersonally. Throughout the history of China, the "character of Junzi" has always been regarded as a model personality among scholars.

The Development of Modern Personality Psychology in China

The Start of Modern Personality Psychology in China

The first Chinese self-edited psychology textbook for college students, *Psychology Outline* (by Daqi Chen) was published in 1918. The book comprehensively introduced the latest knowledge and achievements in Western psychology at that time, which touched on some of the personality constructs. In fact, before the publication of this textbook, the term "personality" had already been translated into Chinese from a Japanese psychology textbook.

Between 1920s and 1930s, questions such as "whether personality is determined by heredity or the environment" and "whether the success of an occupation is dependent on one's ability or personality" were raised up among Chinese psychological researchers. Against this background, some translated personality tests gradually appeared after 1941, such as Pressey's XO Test of Emotionality, Marston's rating scale of introversion and extroversion, etc. Here, the Chinese Test Association (CTA) played an important role. In 1942, the China Human Affairs Psychology Research Institute was launched at the thirtieth year of the Republic of China, which aimed to study officers' emotional abilities, personalities, and characteristics. Meanwhile, some Chinese researchers had also introduced qualitative personality tests into China, such as the Rorschach Test and the Thematic Apperception Test, after World War II.

Interestingly, a research project was conducted in 1939 by Professor Chuanding Lin to analyze the 34 famous people in Chinese history from the Tang dynasty to the Qing dynasty by using a psychological assessment of 50 traits with 10 different types. The traits included curiosity, struggle, physique, emotion, arbitrariness, gentleness, suggestibility, adaptability, ambition, etc.

The Application of Western Personality Theory and Scales in China

Since the 1960s, a group of students, after completing their study of personality and social psychology in Europe and the United States, returned to Hong Kong and Taiwan, and started to systematically introduce Western, especially American, personality and social psychology theory to the Chinese. The most famous representative in Taiwan was Professor Kuo-Shu Yang of Taiwan University. He cooperated with others to conduct a series of researches on "Chinese personality." For example, he explored in many ways the relationship between social transition of modernization process and the Chinese personality. Since 1965, he focused on national characters, the Chinese and their adaptability to modern life, the relationship between changing values and personality during modernization, the concept and measure of individual modernity, and the impact of individual modernity on social attitude and behavior, etc. In the 1980s, Professor Fanny M. Cheung from the Chinese University of Hong Kong introduced the Minnesota Multiphasic Personality Inventory (MMPI and MMPI-2) into Hong Kong, and then in collaboration with Professors Weizhen Song and Jianxin Zhang from Institute of Psychology, Chinese Academy of Sciences, they conducted several rounds of restandardization of the Chinese version of MMPI-1 and MMPI-2 in Mainland China. Up to now, the instrument is still a primary tool for personality diagnosis by Chinese clinical psychologists.

   Study of personality psychology in mainland China boomed in the 1980s. Mainland scholars introduced and translated a large number of Western personality assessment scales into Chinese, and conducted empirical studies to test the usability of these scales among Chinese people. The scales included EPQ, 16PF, and so on, in addition to the MMPI. The Five Factor Model (FFM) was introduced much later in 1994 in the *Journal of Advances in Psychology* (in Chinese) for the first time, and then the FFM has been extensively used in various situations and samples people. As one of the most popular personality measurements, the five factors were shown to be important personality dimensions for predicting key outcomes in research on subjective well-being, mental health, interpersonal relationships, social behaviors, and various performance evaluations, etc.

The Localization Movement of Chinese Personality Research and the Indigenous Personality Constructs

Personality traits are all related in some ways to the cultural patterns of the people concerned. With the rise in economic development in East and Southeast Asia, scholars from the region, including those from Japan, Korea, Singapore, Taiwan, and Hong Kong, realized that although it was unavoidable to learn, imitate, and borrow Western personality theories during the early stages of the formation of Asian theories of personality in general and Chinese theories in particular, it would be inevitably biased if only Western theories and tools were used to describe and measure the Chinese, which may lead to "false consensus effect" or "intercommunity cheating." Therefore, the "localization movement" of distinctive Chinese personality research was developed vigorously. Some representative works included David Yau Fai Ho and Ruey-Ling Chu's research on face; Kwang-Kuo Hwang and others' research on *Renqing* (relationship orientation); Kuo-Shu Yang, Kuang-hui Yeh, and others' research on filial piety; Kuo-Shu Yang and others' research on individual traditionalism; Michael H. Bond, Kwang-Kuo Hwang and others' research on harmony; Michael H. Bond and others' Chinese Value Survey; Chung-Fang Yang and others' research on *zhongyong* (the Doctrine of the Mean); Fanny M. Cheung and others' research on interpersonal relatedness and Guanxi (relation orientation) in management, etc. Listed below are some of these important Chinese indigenous personality constructs that have been studied empirically.

Renqing (Relationship Orientation)

Renqing means a reciprocal relation between individual persons. When individual is engaged in a social exchange, he/she has some resources to give to others, and expects to establish a long-term relationship with others instead of exchanging some other resources from others in return. The resources include not only money, valuable goods, and services, but also affect, social support, even love. It is demonstrated that Western individuals' interpersonal relations are based more on the principle of equal exchange. They prefer something in return equivalent to what they have given to others. So, the relationship emphasizes much more rationally debt-avoidance and fairness. In contrast, Chinese *Renqing* features a long-term and continuous relationship, so that people in such a relationship should not want to get the resources they like immediately, and even more, they sometimes tend to give more to others and want nothing back from them. Therefore, raising an invoice or squaring an account is considered an unkind and an impersonal manner of interpersonal behaviors.

That is why the Chinese *Renqing* strategy is to maintain a dynamic balance in the relationship network. As an indigenous personality trait, *Renqing*, a culturally relevant Chinese characteristic has permeated deeply through individuals, who, in most cases, will abide by the cultural norms including modest etiquette, resources exchange, cooperating and maintaining relationships, nepotism, etc.

Face

In Chinese culture, face is a dominant concept to guide interpersonal behaviors. In contrast to the Western concept of face, the concept of face in Chinese culture is more interpersonally connected. Face is not only related to an individual's status level in the social relation network, but also involves the possibility that he or she might be accepted by others and what the privileges are that he or she might have. Therefore, it is important for the Chinese to "care about their face" because others' opinions are closely associated with their self-esteem. People not only pursue a good face in normal times but they are also positively dedicated to contend for face in case of losing their face. "Saving face" and "earning face," or even "give face" get a constant training in the "hierarchical order" in Chinese culture.

Harmony

Respecting and upholding harmonious relations with other side of the world, with other people, and with oneself has always been hailed as a fine Chinese tradition in philosophy and culture. Harmony is precious; endurance makes peace; make concessions to avoid trouble; stand aloof from worldly success; live in harmony; always be calm; a contented mind is a perpetual feast; avoid offending others etc. All of these are fundamental principles for the Chinese to conduct themselves. Therefore, Chinese harmony is reflected in two ways: first, it is inner calmness and harmony and second, the interpersonal concordance.

Exploration of the Personality Structure of Chinese People: CPAI and the Sixth Personality Factor

The goal of the CPAI was to construct an inventory that is relevant to the Chinese cultural context, and would also meet the scientific psychometric standard expected of established assessment instruments, in order to provide Chinese society with a reliable, valid, and useful personality measure. CPAI was initiated in the early 1990s, and its development has been continuing in Hong Kong and in Mainland China. Professors F. Cheung, W. Song, K. Leung, and J.X. Zhang, and others, led the research to devise a second version of CPAI.

The CPAI was constructed by adopting a combined etic-emic approach – an approach that takes into account both universal and culture-specific aspects of the Chinese personality. The CPAI included four normal personality dimensions: social potency, dependability, accommodation, and interpersonal relatedness. What is worth mentioning is that "interpersonal relatedness" (IR) contained many indigenous personality constructs. It showed the pattern of behavior and the cultural connotation of how Chinese people "conduct themselves" in society, such as caring about relationship orientation, avoiding face-to-face conflicts, maintaining surface harmony, while everyone was able to maintain their "face" in the society. Interestingly enough, the joint factor analysis of CPAI and FFM showed that while the four CPAI factors overlap with the Big Five, the IR factor from CPAI stood out as

an independent factor in addition to the Big Five Personality Model which constitutes a "Big Six" structure that can be used to describe and explain the Chinese personality and behavior. Up to now, CPAI-2 has been translated into English, Japanese, Korean, Vietnamese, Dutch, and Romanian, etc. After applying the translated versions to corresponding cultural groups, the IR factor can still be retrieved in some non-Chinese samples. The utility of the IR factor has obtained noticeable empirical support and application validity.

Though the CPAI is aimed to be applied to other cultural backgrounds, the effective use of the IR inventory in both Chinese and Western cultural backgrounds indicated that it can reveal some deficiencies in Western personality theory and evaluation, which is inclined to focus on intrapsychic and individual traits related to heredity, thereby ignoring the important fields involving social culture and interpersonal relations. These findings prompted the CPAI team to consider the cross-cultural applicability of CPAI-2, which was later renamed the "Chinese Personality Assessment Inventory" as the "Cross-cultural (Chinese) Personality Assessment Inventory." The CPAI-2 is widely recognized to be a useful personality measure that covers culturally relevant dimensions of the Chinese personality, which demonstrates incremental validity beyond Western models of personality.

Other Personality Researches in Contemporary China

The Seven Factor Personality Model

Based on adjective descriptions, a personality test (Qinnian Zhongguo Personality Scale, QZPS) was compiled to measure the Chinese personality, which resulted in a seven-factor structure of personality, including the factors of Extraversion, Human Relations, Behavior Styles, Talents, Emotionality, Kindness, and Ways of Life. The advocates of the model (Dengfeng Wang and others) believed that the difference between the Seven Factor and the Big Five Personality Models demonstrated exactly the well-documented difference between the Chinese and Western people. They concluded Western personality scales are unsuitable for measuring the Chinese personality.

Self-Supporting Personality

Self-supporting personality is valued by Chinese traditional culture, and it is considered as a positive personality construct and an important part of sound personality. Self-supporting personality is a comprehensive personality factor featuring independence, initiative, responsibility, flexibility, openness, etc., which exist in both individual and interpersonal lives when people settle problems during their survival and development. Professors Xiting Huang and Lingxiang Xia developed corresponding Self-Supporting Personality Scales based on the personality construct. Corresponding research shows that the self-supporting personality has 10 traits; all of which are relatively independent and can be divided theoretically into two factors: interpersonal independence and personal independence. The interpersonal independence contains five traits: interpersonal self-reliance, interpersonal initiative, interpersonal responsibility, interpersonal flexibility and interpersonal openness. Personal independence also consists of five traits: personal self-reliance, personal initiative, personal responsibility, personal flexibility and personal openness.

Personality Psychology in Central and South America

Andrés J. Consoli[1], Héctor Fernández-Álvarez[2], and Mercedes Fernández Oromendia[3]

[1] *University of California, Santa Barbara*
[2] *Fundación Aiglé*
[3] *University of California, Los Angeles*

Central and South America encompass a large geographical area with great diversity in their populations. Not including the Caribbean, there are 18 countries within both regions that have an estimated total population of 600 million people (United Nations Demographic Yearbook, 2015). Although Spanish is the official language of the majority of the countries in both regions, many other languages are also spoken throughout Central and South America including Dutch (Suriname), English (Belize, Guyana), French (French Guiana), and Portuguese (Brazil). In addition, many people across both regions speak an indigenous language, sometimes in conjunction with and sometimes instead of the official language. It is estimated that over 4.5 million people speak a Mayan language in Central America. In Guatemala alone, there are 21 indigenous Mayan languages as well as two additional languages: Garífuna and Xinca. In South America, approximately 350 languages are spoken. Close to 20 million people speak an indigenous language in that region, with the most widely used languages being Quechua (actually a family of languages), spoken in Bolivia, Ecuador, and Peru; Guaraní, an official language of Paraguay also spoken in Argentina, Bolivia, and Brazil; and Aymara, which is spoken in Bolivia, Chile, and Peru.

Religion in Central and South America has historically been predominantly Catholic. Catholicism continues to have a strong presence in the region, although Protestant denominations have been increasing in numbers since the latter part of the twentieth century. In addition, there has been an increase of people that do not identify with any religion. The racial, ethnic, and national background of people in Central and South America varies greatly depending on the region. European, African, and indigenous backgrounds are the most common, but there are also descendants of Arabs, Jews, Chinese, and Japanese. Estimates of indigenous populations vary greatly depending on how indigeneity is defined and measured. There is also a wide range of socioeconomic inequities among people and countries in the region and a sizable portion of the population live at or below the poverty level. For example, in 2015 the highest gross domestic product (GDP) per capita in the region was $31,700 (Chile) while the lowest was $4,850 (Honduras). Meanwhile, 28% of the

total population lived in poverty and 12% lived in extreme poverty or indigence in 2014. It should be noted that the percentage of people living in poverty in some countries, mostly in Central America, exceeded 50% (Guatemala, Honduras, Nicaragua), while in other countries, mostly in South America, it was below 10% (Argentina, Chile, Uruguay). Given the wide range of languages, religions, ethnicities, and GDP across the region, developing an entry on personality psychology that captures the great diversity within Central and South America is a sizable challenge.

As can be expected considering the vast diversity that characterizes Central and South America, there is not a single, commonly agreed on definition of what constitutes personality or personality psychology in the region. In fact, the diversity of people in the region is mirrored in its psychology as a discipline. While primarily influenced by European psychology and later by psychology from the United States, there are also a range of psychologies that are readily identifiable as Latin American, which, in turn, have contributed to the understanding of personality and personality psychology in the region. Perhaps most noteworthy in the personality psychology literature from Central and South America are the tensions between alternating emphases, such as individualism versus collectivism; cultural universals (etic and imposed etic) versus culture-specific (emic) dimensions; individual traits versus national character; the individual versus contexts and interactions; nomothetic versus idiographic approaches; the use and standardization of personality inventories versus the recognition of subjectivity, life narratives, and cultural differences within a historical-cultural perspective; the pursuit of cultural adaptation versus cultural transformation, and many others.

Personality Traits and Assessment

Many psychologists in Central and South America have explored and contributed to the literature on personality traits, be that at the theoretical level or at the use and adaptation level of a considerable range of personality inventories. The Big Five personality traits or Five Factor Model (i.e. neuroticism, extraversion, openness to experience, agreeableness, and conscientiousness) have received sizable attention and psychologists such as Chilean Enrique Barra and Argentine Marcos Cupani and collaborators have used and adapted the corresponding assessment instruments (such as the NEO-PI-R, IPIP) to assess life satisfaction and psychological well-being, predict school performance, particularly mathematics, and facilitate vocational orientation and career choices. Some cross-cultural studies in the region have shown that the five-factor structure is retained across groups and captures peoples' emphases on openness in the region, contrasted with other parts of the world. Other studies have challenged those findings based on the markedly limited representativeness of the samples utilized in most studies made of largely literate, college students, and urban people. These other studies have offered alternative factor structures such as prosociality, and industriousness based on their findings from different samples that included illiterate and indigenous groups (e.g. Gurven et al., 2013).

Central and South American psychologists have also utilized Eysenck's Personality Model, together with its Questionnaire and Scales (earlier EPQ, later EPS, including psychoticism, extraversion, and neuroticism) in an effort to assess individual differences in

the region. Sybil Eysenck, the widow of Hans Jürgen Eysenck, together with several Latin American colleagues such as Nicholas Tarrier from Brazil and María Asunción Lara Cantú from Mexico, conducted cross-cultural studies using the EPS in the latter part of the twentieth century. The findings from those studies underscore limited cross-cultural differences or limitations in the instrument to detect them. Vanina Schmidt from Argentina, Walter Gallegos from Brazil, Clemencia Montaña de Barragán from Colombia, Esperanza Bausela Herreras from Mexico, and Sergio Domínguez Lara from Peru, among others, have assessed Eysenck's theory, and some of them have used its assessment instruments successfully in Latin America.

Beyond the assessment instruments derived from the Five Factor Model and Eysenck's Personality Model, Central and South American psychologists have also utilized and adapted Cattell's Sixteen Personality Factor Questionnaire as well as clinical personality inventories such as the Minnesota Multiphasic Personality Inventory and the Millon Clinical Multiaxial Inventory. Moreover, they have avidly employed projective instruments such as the Thematic Apperception Test and the Rorschach.

Personality and Culture

Psychologists in Central and South America have also pursued the development of indigenous dimensions and measures framed by theories such as ethnopsychology and *mestizo/a* psychology that affirm indigenous (emic) perspectives and out of concern with imposed etic instruments. Rogelio Díaz-Guerrero and his son, Rolando Díaz-Loving, together with Isabel Reyes-Lagunes, all from Mexico, are readily identifiable as three main contributors to this important literature seeking to identify indigenous constructs (e.g. self-subordination, nonassertiveness), self-concepts, and behavioral exemplars as expressed in cultural norms through sayings, maxims, or proverbs ultimately referred to as historic-sociocultural premises. Some of these scientific efforts evolved into concepts such as national character, in an attempt to capture the dialectical relationship between culture and personality (Díaz-Guerrero, 2003).

In their efforts to make sense of the relationship between culture and personality, Central and South American psychologists have resorted to Geert Hofstede's cultural dimensions, particularly individualism-collectivism, Harry Triandis' tight and loose cultures, David Magnusson's holistic and interactionist model, and, more recently, Shalom Schwartz's human values. Over the course of these efforts, Latin American psychologists have emphasized subjective experience, childrearing and family life, friendships, social interaction, socialization, and interdependent selves in contrast to private, autonomous, independent selves in their attempts of not only describing but, most importantly, understanding and conceptualizing personality. Furthermore, these progressive views on personality have resulted in critical analyses of power structures and socio-political processes that bring about human suffering and perpetuate social injustices. Some Central and South American psychologists, influenced by the work of educator Paulo Freire, have sought to foster conscientization (the ongoing process of acquiring a critical consciousness), self-determination, and community agency to redress oppression and exploitation through emancipatory practices that are articulated in liberation psychology (Martín-Baró, 1996).

The advent of qualitative research methods has transformed knowledge generation in personality psychology where instead of asking participants to respond to pre-formed items they now share their own perspectives and construction of reality in the context of semistructured interviews and community based participatory action research.

Personality Disorders

Personality disorders have not been considered a central focus in the general field of psychopathology or in epidemiological studies in Central and South America. In fact, some of the best-known studies on the prevalence rates of mental health disorders in the region do not include data on personality disorders. The field of psychology in Central and South America has only very recently begun to study these disorders. For a long time, personality disorders were primarily within the field of psychiatry, and particularly from a psychodynamic perspective. For example, the region's representative to the International Society for the Study of Personality Disorders, Argentine psychiatrist Néstor Koldobsky, published one of the first specific texts on the subject as did fellow psychiatrists Francisco Berdichevsky Linares and Gustavo González Ramella.

Since 1980, however, Central and South American psychologists in clinical practice have been actively engaged in addressing personality disorders despite the limited psychological publications in this area. This is in part because in many countries in the region, clinical psychologists have utilized behavioral modification, an approach that has focused primarily on conditions such as mood disorders. Colombian psychologist Rubén Ardila has been a pioneer in this area, founding the journal *Avances en Psicología Clínica Latinoamericana* (Advances in Latin American Clinical Psychology, later Advances in Latin American Psychology) in 1982.

When addressing personality disorders, psychologists have had two primary sources. One source involved psychoanalysis, particularly the work of Otto Kernberg, an Austrian who emigrated to Chile in 1939 at age 11 and became a psychiatrist and psychoanalyst who then immigrated to the United States in 1961. More recently, it has been the work of Peter Fonagy, a Hungarian-born British psychoanalyst and clinical psychologist. Numerous authors across the region, including Erika Benítez Camacho and collaborators in Mexico, as well as María Josefina Escobar and collaborators in Chile, have adapted and further developed these psychoanalytic models. The other primary source has been marked by the strong influence of US psychological models such as that of Theodore Millon and, more recently, Jeffrey Young and Marsha Linehan. These models have been furthered by Latin American psychologists such as Edgar Rodríguez Vílchez in Peru and Jan Luiz Leonardi in Brazil.

The emphasis on personality disorders in Central and South America is growing, primarily as a result of the integrative movement in psychotherapy. For example, Ecuadorean psychologist Lucio Balarezo Chiriboga has developed an approach that places personality and personality disorders as the central foci in clinical work. Chilean psychologists Roberto Opazo Castro and Verónica Bagladi Letelier have developed a conceptual scheme on personality disorders based on their overarching, integrative approach. Argentine psychologist

Héctor Fernández-Álvarez has made several contributions to the study and treatment of personality disorders, such as the conceptualization of pathological affective dependence (Fernández-Álvarez, 2000). He has published, together with Spaniard psychologist Amparo Belloch Fuster, a book on the treatment of people experiencing personality disorders (Belloch Fuster & Fernández-Álvarez, 2010).

Most recently, Central and South American psychologists have pursued specific research topics such as the relationship between personality traits and personality disorders, and between anxiety disorders and personality disorders. Chilean psychologist Mariane Krause leads a research program on depression and personality disorders known as MIDAP, together with colleagues from Europe and the United States.

The *Asociación Psiquiátrica de América Latina* (Latin American Psychiatric Association) developed the *Guía Latinoamericana de Diagnóstico Psiquiátrico* (GLADP, Latin American Guide for Psychiatric Diagnosis) in 2004 and revised it in 2012 (GLADP-VR). The guide offers a person-centered integrative diagnostic model and includes personality disorders. It emphasizes the importance of a comprehensive evaluation that pays particular attention to ethnic, cultural, and social dimensions as well as contextual factors.

Personality Psychology from an Islamic Perspective

Amber Haque

Al Ain, United Arab University, United Arab Emirates

The Topic's Intellectual and Social Context

Personality in Islam is viewed as a multidimensional entity comprised of body, mind, and spirit that interact with one another and constitute an individual human being. Just as the universe and celestial bodies possess a nature of their own, humans also possess their own nature and act in certain ways. In the Qur'an, the Muslim holy book, humans are encouraged to reflect on the signs within and outside themselves so they can know their real self and their relationship with their Creator. Islamic injunctions prescribe ways of constructing a personality akin to the commandments prescribed in the Qur'an. In Arabic, the term "personality" translates to *shakhsiya* and "psychology" to *ilm an-nafs*. *Shakhsiya* is used to describe individual traits/characteristics and was traditionally addressed in Islamic philosophy. Referring to certain verses of the Qur'an, Utz (2011) points out that "... humans are endowed with genetic codes that guide the development of the brain and elements of it are apparent from birth. Within a few months after birth, temperamental individuality is established. This character then influences a person's reactions to and interactions with the environment" (p. 98).

Early Muslim scholars wrote extensively about psychological concepts, but with the passage of time there was a constant decline in the interest and refinement of Islamic perspectives on personality (Haque, 2004). One of the major reasons for this neglect in the understanding and conceptualization of human nature from an Islamic perspective was the opinion of prominent Muslim scholars of the time that whatever is supposed to be known by Muslims was conveyed by Prophet Mohammad and to go beyond that knowledge may constitute innovation, which is prohibited in Islam. Although scholars acknowledged that this opinion could be true for religious matters, it led to a freezing of Muslim scholarship in many areas of knowledge (Sulaiman, 1990). Additionally, with the lapse of time and dominance of Western thinking, Muslims became followers of Western paradigms to the extent that Islamic views of personality and psychology became totally dormant in the Muslim world.

Major Dimensions of the Topic

From an Islamic perspective, the concept of personality is derived from human nature, which is considered dialectical. On the one hand, there are biological needs and instincts of a person and on the other hand there are spiritual ones. The psychological component of human nature is referred to as the *nafs* (self) that overlaps body and spirit and serves as a mediator between the two. When an individual is fixated mostly on biological needs, the *nafs* is referred to as *nafs al-ammarah.* Pure indulgence in biological needs becomes a barrier in the growth of psychological and spiritual domains of personality. The mind or psychological domain consists of three subdomains, intellect (*aql*), freewill (*iradah*), and intuition (*qalb*) and as they interact, an individual takes on the attributes of both body and spirit. The spirit can connect the individual with the Creator but an attachment to the biological may distance the person from Him. The polarity between biological and spiritual is mentioned in the Qur'an and that an overattachment to the biological and material can make humans become lower than animals. However, an attachment to the spiritual can elevate the position of humans higher than angels. This is because humans can exercise their freewill and acquire characteristics of a true believer. Islam emphasizes a balance in all three domains that leads to an Islamic personality. While the body, mind, and spirit constitute the total personality, the body perishes at death but the spirit transcends into the next world and faces consequences of its action in this physical life. So, in essence, it is the psychological domain that will eventually lead humans to good or evil in the hereafter. The entire notion of human personality is rooted in the Tawhidic paradigm, which is a belief in the Oneness of God (Allah) and practicing the Islamic faith.

Changes Over Time in the Topic and Its Treatment

The written accounts on the description of human nature and personality by Muslim scholars continued from 800 CE until 1100 CE. Many scholars contributed to the debates on philosophy of mind and soul, but in the interest of brevity, a few names deserve mention.

Al Kindi (d. 866) is the first known Muslim scholar who wrote about individual differences and personality issues including cognitive strategies to combat depression. Ibn Sina (d. 1037) discussed the mind–body relationship, sensation, perception and other related aspects of human personality. Al-Ghazali (d. 1111) wrote extensively about human nature and emphasized that all psychological phenomena originate with the self. He described the nature of human soul and causations of psychopathology. The theories formulated by these early scholars were curative in that they prescribed cognitive and spiritual ways of combating psychological disorders. After 1100 CE not much was written or recorded and a very meager amount of literature is available in the English language (Haque, 2004).

As a result of the colonization of Muslim countries and Western education, the importance of Western scholarship took roots in Muslim minds. This has not only detached them from their own intellectual legacy, but it has also made them propagate Western views of knowledge in all areas including the humanities and social sciences. Works that first started to come out of the modern Muslim world on human personality started in Egypt. Two major works published were *Personality and Its Measurement* (Meleika, Ismail, & Hana, 1959) and a translation of the textbook *Psychology of Personality* by Notcutt (1959). The first

text covered personality theories and assessment and descriptions of MMPI. The second served as a textbook for university students in the Arab world (Ahmed & Gielen, 1990). In the 1950s and 1960s, many books on psychoanalysis and behavioral psychology were translated for use in Egyptian universities. For example, Ghoneim translated Lazarus's popular textbook *Personality* (1981) and Abdel Khaleq (1981–1983) edited three volumes *of Research in Behavior and Personality*. There was also the development of personality questionnaires by Abdel-Khalek (1993). Shalaby (1991) also came up with a personality theory but until now there is no well-developed theory of personality from an Islamic perspective. An attempt by Haque and Yasien (2009) in their edited work *Psychology of Personality: Islamic Perspectives* came as a breath of fresh air! Psychometric tests were also developed in Egypt in two main areas: Eysenck's factors of neuroticism and extraversion and Cattell's conceptions of personality factors (Abdel-Khalek et al. 1986). Early in the 1950s some Arab psychologists like Haqqi (1979) developed personality tools but the 1960s and 1970s witnessed an overwhelming trend in translating US and British questionnaires. Some locally standardized personality tests started to show up in the 1980s (e.g. Souief, 1985). In the osther Arab/Muslim countries, the scenario was less than satisfactory as psychology as a discipline was introduced very late and indigenous views were not considered evidence-based; so Western theories continued to dominate.

Current Emphases in Work on the Topic in Research and Theory

Very little, if any, work on personality theories in the modern era from an Islamic perspective is offered by the Muslim world but there is significant activity in the area of standardized personality test developments. The establishment of the *Journal of Muslim Mental Health* has led to much research discussing theories and test development for Muslims. There are psychology journals in different parts of the Muslim world but they are based largely on Western paradigms. Most of the journals in the Muslim world are published in local languages making their usefulness for international audiences quite minimal. The International Islamic University of Malaysia (IIUM) boasts a unique psychology program based on the integration of science and religion. This initiative came out of the efforts to "Islamicize" knowledge (make knowledge compatible with the Qur'an) in an effort led by Faruqi (1990). In 1998, an entire issue of the *American Journal of Islamic Social Sciences* was devoted to Islamic perspectives in psychology. In more recent years, articles discussing Islamic views of personality and the need for promoting indigenous theories have appeared in some prominent journals (Haque & Keshavarzi, 2014; Keshavarzi & Haque, 2012; Murken & Shah, 2002; Haque, 1998).

Future Directions in Research, Theory, and Methodology

While efforts are underway to collate research, Muslim psychologists in different parts of the world need to advance Islamic personality theories, research, and methodology in detail and in a way that makes literature available to an international audience. A meta-analytic study may be a good start to chart a plan for the future. Psychologists interested in

Islamic perspectives have to decide the way forward, including working with Islamic theologians who are more familiar with the divine texts and their interpretations. While it is best to start from the Qur'an and Hadith, the two main theological sources, there are also other materials available from which to extrapolate (Haque, 2004). Islamic psychology needs to be promoted as a discipline housed in an accredited international university or institute (Haque, 2000). A scientist-practitioner approach is needed with grants and scholarships for motivated researchers and students. A special section on Islamic perspectives of personality could also be introduced in prominent international conferences and seminars. These steps are necessary and will only result in the positive development of a field that is of much import as a result of growing interest and need for multicultural psychology.

Tiger Mother

P. Priscilla Lui

Southern Methodist University

Origin and Definitions

"Tiger mothers," and by extension, "tiger parents," are characterized as highly demanding of their offspring in terms of academic performance, accomplishments in a narrow range of culturally valued extracurricular activities, and family obligation. This parenting style implies that there is little overt warmth or emotional support toward the offspring. Rather, it connotes an emphasis on using coercion and shaming to promote offspring's success and to preserve strict hierarchy in the parent-offspring relationship. The term "tiger mother" was popularized in the *Battle Hymn of the Tiger Mother* (Chua, 2011). In this book, author Amy Chua, a second-generation Asian American law professor, described her approach to tiger parenting her Asian and Jewish mixed-ethnic daughters. This kind of parenting has been considered to be rooted in the belief that offspring can rise to meet challenges and achieve the highest levels of academic success in response to the very high standards and expectations set forth and reinforced by harsh parenting behaviors. Tiger parents also have been depicted as de-emphasizing self-esteem, autonomy, and social skills in their offspring. These parenting behaviors have since been referred to colloquially as Chinese, or more broadly Asian, parenting. Tiger parenting has generated (inter)national attention and controversies because of the prescriptive nature of supposed "Asian" parenting practices and their intended contrast to mainstream Euro American parenting styles. Research into mainstream parenting styles and child socialization among Asian families has illuminated the socio-cultural patterns that are both consistent and inconsistent with tiger parenting, as well as its impact on offspring development.

Characteristics of Tiger Parenting and Mainstream Parenting Styles

Contemporary research suggests empirical support for the existence of tiger parenting as one style in a large sample of Chinese Americans. Based on profile analyses, tiger parenting indeed shows strong monitoring, control, hostility, punitive behaviors, and shaming,

and lower warmth, especially in comparison to a "supportive" parenting style identified in the same sample (Kim, Wang, Orozco-Lapray, Shen, & Murtuza, 2013). At the same time, tiger parents show greater warmth, reasoning, democracy, and lesser hostility and punity than those characterized as "harsh" parents. Contrary to Chua's depiction of tiger parenting as the predominant parenting style in Asian American families, less than 30% of the adolescents in the sample describe their parents as tiger parents.

Decades of mainstream developmental psychological research has come to characterize four major parenting styles. According to Baumrind's classic typology (1966, 2012), *authoritarian* style refers to parenting practices that shape and control offspring's behavior against a set of rigid standards, in which obedience is highly valued, and free will and autonomy are restricted. Authoritarian parenting differs from *authoritative* style: the former is generally marked by punitive practices and hostility, whereas the latter is defined by parenting practices to guide offspring's behaviors and development with reason and issue-oriented discipline. Both autonomy and conformity are valued, but the set of standards is rather flexible among authoritative parents. *Permissive* parenting style is characterized as nonpunitive and accepting, with few demands for obedience. Compared to either authoritative or authoritarian parenting, permissive parents do not hold their offspring to a well-established set of standards; the offspring often are left to their own devices in regulating their behavior. Subsequent research further distinguishes two subtypes of permissive parenting. Although similar in the low level of demandingness and expectations of their offspring, indulgent parents are attentive and responsive to offspring's emotional needs, whereas neglecting parents are not. As illuminated by this foundational body of research on parenting, a balance in discipline and promotion of offspring's individuality and self-regulation is critical to the optimal adjustment among Euro American offspring.

In contrast to these parenting styles typical in mainstream American cultures, tiger parenting is marked by greater engagement in harsh discipline (both in terms of corporal punishments and verbal hostility), shaming via explicit social comparisons among offspring and peer achievement, placing heavier emphasis on academic performance over social, physical, and autonomy development, and highlighting interdependence within the family. Beyond simply describing parenting prototypes such as authoritative and tiger parenting, psychological research also highlights the importance of contextualizing parent-offspring interactions within the meaning and goals of parenting practices across ethnocultural groups.

Effects of Parenting on Offspring Outcomes: Multicultural Considerations in the Goals of Socialization

Tiger parenting has been invoked in the discussion of Asian Americans as "model minorities," who overcome social and economic adversity with uncomplaining hard work (Lui & Rollock, 2013). Chua brought new prominence to the concept by also identifying a generational decline in Asian Americans' accomplishments, which she attributed to Asians' abandonment of tiger parenting practices as they adopt American mainstream norms. Empirical studies have shed light on the validity of this claim from two perspectives. First, recent immigrant Chinese mothers with young children are more likely to adhere to tiger parenting behaviors. As they spend more time in the United States, they report being

increasingly flexible in their parenting behaviors, and more mindful about fostering their children's independence, self-esteem, and emotional development (although not necessarily devaluing interdependence). Second, the prevalence of tiger parenting has been found to vary across developmental epochs. While children are more likely to describe their parents as tiger parents than parents themselves, by late adolescence and emerging adulthood, the percentage of offspring reporting having tiger parents drops from 30% to under 20% (Kim, Wang, Shen, & Hou, 2015). These findings echo the acculturation-gap distress literature on parent-offspring discrepancies in beliefs about parenting practices, acculturation behaviors, and cultural values, which may in turn lead to greater acculturation-based conflicts unique to immigrant families (Lui, 2015).

Perhaps the most important and controversial assertion by Chua is that tiger parenting produces direct, positive benefits in terms of superior academic achievement among young Asian American students relative to their non-Asian peers. Systematic studies of the developmental consequences of tiger parenting have yielded paradoxical results across academic and psychosocial outcomes (e.g. Cheah, Leung, & Zhou, 2013; Hsin & Xie, 2014). Whereas tiger parenting has shown effects similar to supportive parenting in promoting offspring's academic achievements, offspring with tiger parents report less family obligation, and greater feelings of academic pressure, alienation from parents, and higher levels of depressive symptoms. Offspring of tiger parenting seem to have better psychosocial outcomes than those with harsh parents, in terms of lower depressive symptoms and greater sense of alienation from and obligations toward parents. In contrast, authoritative parenting styles seem to encourage academic achievement among middle-class Euro American offspring, but has been shown ineffective by itself in influencing academic development of Asian (and African) American offspring (e.g. Fu & Markus, 2014).

When compared against the negative consequences of harsh and authoritarian parenting and favorable consequences of supportive and authoritative parenting among Euro Americans, tiger parenting among Asian Americans takes on differential meanings and impact when contextualized in terms of cultural differences in the self and goals of socialization (Chao, 1994; Darling & Steinberg, 1993). For example, research disentangling the components of tiger parenting has shown that high levels of parental monitoring do not predict depressive symptomatology and academic motivation among Asian (Hmong) Americans. Rather, low levels of parental monitoring in the context of high levels of acculturation-based intergenerational conflict predict more depressive symptoms and lower self-esteem (Supple & Cavanaugh, 2013).

Remaining Research Questions

Further understanding of how tiger parenting influences offspring development depends on scientific examinations of its adaptive value in an Asian context. The assertions of the characteristics and influences of tiger parenting lack a nuanced perspective within diverse groups of Asian Americans. There are at least 23 countries/regions of origin that are represented among individuals who are classified as "Asian Americans." In addition, how parenting styles and practices correlate with parents' acculturation to the mainstream and/or enculturation to their ethnic heritage cultures remains understudied. There has not been a solid empirical basis to the "generational decline" discussed in the *Battle Hymn of the Tiger*

Mother. This observation by Chua may be attributable to differential goals of socialization and emphases on offspring developmental outcomes, or a function of socioeconomic status. Hence, the psychological literature can benefit from better understanding of the differential influences of acculturation, socioeconomic status, and ethnocultural membership on tiger parenting.

Person-centered approaches such as profile analysis have been helpful in mapping out the typology of parenting in Asian American ethnocultural groups. Qualitative studies using interviews and focus groups also have shown their merits of more nuanced understanding of Asian American parents and offspring's perception and experiences with tiger parenting and other styles. The field has advanced from etic approaches of comparing Asian American samples against Euro American mainstream samples to emic approaches that emphasize group-specific experiences. Moving beyond the study on the typology of parenting behaviors, including those of tiger mothers, research should unpack the unique influences of the "active ingredients" of parenting practices within these configurations. For example, the literature is unclear as to whether psychological control (e.g. shaming, reinforcement of high standards for excellence) results in high academic achievement in Asian American offspring. Additionally, little is known about the emotional contexts (e.g. parents' expression of warmth or offspring's emotional connection toward the parents) in affecting the effectiveness of parent behavior.

Furthermore, there is a lack of knowledge regarding the appropriateness of tiger parenting across developmental epochs. Studies could benefit from cross-sectional designs across developmental cohorts to examine prevalence variations in tiger parenting and this parenting style's impact on offspring's psychosocial functioning. Research that uses longitudinal designs also can delineate the change trajectories of parenting practices and their associations with offspring's developmental outcomes. Finally, the current empirical investigations have focused mainly on the attitudes and behavioral practices as parental characteristics; fewer have examined how offspring's intra- and interpersonal characteristics influence parents' behaviors. Research should aim to bridge the connection between individual differences in parenting and offspring behaviors to better ascertain the complex interplay among these factors.

Native Hawaiian Personality

Alyson Burns-Glover[1] and Laurie "Lali" D. McCubbin[2]

[1] *Pacific University, Oregon*
[2] *University of Louisville*

Theoretical Framework and Conceptualization

Before conceptualizing personality or sense of self among Native Hawaiians, it is important to clearly define Native Hawaiians in the context of history and place. Native Hawaiians (*Kānaka Maoli*, the "true" or "real people") refers to the indigenous people of the Hawaiian Islands. Native Hawaiians established their own monarchy, government, constitution, and had international policies and treaties establishing Hawai'i as a nation. The Kingdom of Hawai'i had a history of encouraging and accommodating immigration and intermarriage that informs Native Hawaiians' definitions of identity and personality as well as what "being" and "acting" Hawaiian means.

In 1893, a group of American businessmen, assisted by the US Navy, overthrew the Hawaiian government. An overwhelming majority of Native Hawaiians (an estimated 38,000 of 40,000) protested the loss of their sovereign nation. Colonization of their nation included suppression of traditional social and spiritual practices, language use, and imposition of Western concepts of blood-quantum and nuclear family structures that continue to affect Native Hawaiians' sense of identity and expression of "traits" as they are understood in Western psychology. In *Aloha Betrayed*, Noenoe K. Silva provides a complex overview of the effects of colonization on Native Hawaiian identity. The effects of this cultural trauma as well as the centrality of family support to individual differences in resiliency have been the focus of the seminal *Kauai Longitudinal Study*.

Native Hawaiian identity is an ancestry rather than residency. The legacy of Western racial constructions and cultural appropriation, as well as the complex multicultural and multiethnic identities of contemporary Hawaii state residents have meant that identifying "who" is a Native Hawaiian and what makes one "Hawaiian" are consistently negotiated both in the islands and among Native Hawaiians who live elsewhere (Ledward, 2007).

In the 1970s, a cultural renaissance began with two co-occurring events: the protection and rallying of the island of *Kaho'olawe* from bombing by US military and the voyage of the

Hokuleʻa providing evidence of the indigenous Polynesians' skills in navigating the Pacific Ocean. Concomitantly, Native Hawaiian traditions, customs, and practices including the language and hula were and are being revitalized and incorporated into the daily lives of Hawaiians and residents of the Hawaiian Islands. Movements for sovereignty and indigenous rights are occurring also to provide access to the *ʻaina* for subsistence, spiritual and religious purposes, preservation, and conservation.

Geography, Indigenous Psychologies, and Personality

Indigenous psychology involves understanding people through ancestral, social, political and symbolic contexts (Kovach, 2009). Indigenous epistemology is embedded in time, place, and relationships and the *expression of self* is conveyed through genealogy, land, and history (McNeill, McCubbin, & Sevedge, 2017).

The emerging science of *geographical psychology* (Rentfrow, 2014) and the lens of indigenous psychologies attend to the particular historical and social forces from which self and personality arise. These provide a framework for understanding how place and environment create personality systems and relational contexts. This is particularly apt for the understanding of Native Hawaiian cultural influence on the "personality" of the state of Hawaii: "It is axiomatic that the ideals and morals of tolerance, acceptance, diversity and multiculturalism infusing Hawaii society exist because of the *kānaka maoli* or Native Hawaiians" (Andrade & Bell, 2011, p. 1). Rentfrow asserts that these "social founder" effects create social norms, which in turn affect the relative tolerance for and expression of personality traits in a society or region. In Hawaii those norms and social practices are expressed at the societal (see Vandello & Cohen's study of social indicators of collectivism in the 50 United States) and individual level of trait scores amongst Polynesian samples, including Native Hawaiians (Allen, Conklin, & Kane, 2017).

Understanding indigenous epistemology is also important in conceptualizing Native Hawaiian personality especially the relationship with land and sense of place in shaping one's identity. Westerners' conceptualization of land is ownership, property and one's relationship to the land is mastery or dominance over the natural environment. Native Hawaiians' worldview of land is embedded in the value of *lōkahi* meaning unity and balance. One's sense of self and well-being is embedded in harmony with the *ʻaina* (land), *kanaka* (humankind), and *ke akua* (gods). Therefore, to understand Native Hawaiian personality, first one must understand that the concept of self is grounded in the *ʻaina* and social relationships.

This self is defined through one's ecological context (McGregor, Morelli, Matsuoka, & Minerbi, 2003) encompassing family (*ʻohana;* extended family and kin), ancestors, gods, and spirits (*Ke Akua* meaning God and *aumakua* referring to family guardian gods), and natural environment (*ʻaina*). Community plays a central role in defining identity and personality as community cultivates a sense of place where beliefs, values, and cultural practices can be passed on across generations (McCubbin, McCubbin, Zhang, Kehl, & Strom, 2013). This relational worldview of self within an ecological context provides a framework to understanding Native Hawaiian identity and personality.

Native Hawaiian rituals and ceremonies also demonstrate this self-in-relation framework. For example, an *ʻoli* (chant) as an introduction provides information about the context of self-in-relation including one's ancestry and connection to the land. Another example is the blessing of one's home with a Hawaiian name given of the placement of self-in-relation to ʻ*aina* (land), ʻ*ohana* (family), and *aumakua* (ancestors) and time (past and future) (McNeill, et al., 2017). Introductions, naming ceremonies, and sharing of stories are all expressions of identity and self-in-relation through indigenous practices.

Historical Indigenous Self vs. Trait Theory

Any assertions about the content and process of a Native Hawaiian self must be informed by an understanding of the role of cultural trauma in modern Native Hawaiians' conceptualizations of that self. Typically, Western conceptualizations of "self" conceive it as bounded, internalized, and unique (see Culture and Personality). Individual genetic predispositions are offered as evidence of the stability of traits and behavioral tendencies. This a-historical approach to personality cannot be applied to the Native Hawaiian.

A Native Hawaiian self cannot be a singular unit of identity, nor does "relationship" mean the traditional Western idea of human-to-human kinships or friendships. Therefore, one must look to this complex system of unity, harmony, and balance to explain both maintenance and disruption of identity and personality. Such a contextualization necessitates a firm understanding of how cultural and historical trauma have affected the formation and expression of personality: colonization by Westernized practices has affected the ability to maintain functional systems of self, family, and community described above. These practices could impose a chronic state of grief and bereavement on *Kānaka Maoli*, and this inchoate sense of loss often finds its expression in mood dysregulation, ruptures in self-esteem, and conflict with others.

To restore harmony, *lōkahi,* one must address the loss of key features of Native Hawaiian spirituality that reinforced ancestors-nature-human interconnections. Protestant monotheism and abnegation enforced by missionaries occluded important ways in which links to the land (ʻ*aina*), the practice of dance (*hula*), ancestral identification (*aumakua*), and nature-stewardship converged to maintain order (*pono*) within the person and larger community. These disruptions and dislocations interfered with culturally adapted strategies of coping with existential threats via rituals and practices that promoted spiritual balance, resilience, and community cohesion. In the absence of this collective form of psychological defense and "anxiety buffer" the individual will resort to negative strategies for coping (aggression, substance abuse, etc.) that are conceptualized in the dominant culture as individual failings or evidence of mental disorder.

There has been a call to re-conceptualize some Native Hawaiians' ambivalence about their identity from mere internalized oppression to a necessary survival strategy in the face of social and political institutions that have consistently impeded the expression of a healthy Hawaiian self (Kanuha, 2005).

One must be cautious when interpreting an indigenous identity through a Western framework of personality as these theories can be contaminated with a colonial version of history and may perpetuate stereotypes of native people as having marginalized identities. This does not accurately portray the perseverance and vitality of the Hawaiian culture and

identity that is perpetuated through the land and self-in-relation indigenous practices. The past two decades have witnessed a burgeoning interest in the role of Native Hawaiian culture and identity as an important factor in well-being. Such findings have been canalized into a call for a focus on a "healthy Hawaiian identity" rather than the usual focus on deficits and pathologies brought about by cultural trauma and socioeconomic disadvantages. This identity locates itself both in positive health practices and as well as a link to the cultural practices (language, dance, navigation) and values of one's ancestors (McMullin, 2005. The role of culture in the process of resilience is essential to understanding both individual differences in and personality structures common among the Hawaiian people.

Research by and about Native Hawaiians indicates the essential role of relational self and well-being and its impact on physical and mental health. Specifically, one's *'ohana,* culture, values and spirituality play a significant role in mean-making and the construction and maintenance of self and personality (McCubbin & Moniz, 2015). If Native Hawaiian personality is conceived as interdependent, respectful, and harmony-seeking, these "traits" must be understood not as singular human qualities but as deeply cultivated expressions of values, connections with the land, and interrelationships that sustain the health and well-being of a people.

Future Directions for Research and Theory

When Native Hawaiians are correctly identified (cf., disaggregated) in research it is usually to test and report on disparities (e.g. higher rates of perinatal depression, depression, poorer educational outcomes). There is a paucity of research on individual differences (cf., traits), or how the place-based and relational self embedded in the culture might affect the expression of or relative frequency of such traits.

This focus does identify important needs of the community, but it is also important to identify and promote the emerging "educational healing" and culture-as-cure approaches that locate mental and physical health in positive ethnic identity, and expression of native values are becoming more evident in approaches to the assessment of personality and the identification of an ecologically embedded self.

Personality and Aging

Susan Krauss Whitbourne[1] and Jennifer Lodi-Smith[2]

[1] *Canisius College*
[2] *University of Massachusetts Amherst*

Once thought of as stable, personality development in adulthood is increasingly being recognized as reflecting processes of change over time. Researchers are beginning to gain a new understanding of how personality evolves throughout life in the context of the biological, cognitive, and social changes associated with aging, which both affect, and are affected by, personality.

It is important when interpreting the results of studies on aging and personality to point out that a number of investigations use cross-sectional methodology according to which cohort differences may account for apparent age differences. Conversely, longitudinal studies reflect patterns of age changes that may also reflect selective survival of, for example, individuals higher in emotional stability. Therefore, sequential studies that account for both cohort and survivor effects are preferred, though data from these studies are not always available. Where possible, we draw from longitudinal studies which, though biased by selective survivor and time of measurement effects, are preferred over cross-sectional studies.

The most thoroughly studied changes in personality traits are based on the components of the Five Factor Model, namely conscientiousness, agreeableness, emotional stability (neuroticism), extraversion, and openness. These personality traits show normative patterns across age groups and over time reflecting the plasticity principle that changes can and do occur in personality traits throughout the adult years. Additionally, in accordance with the maturation principle of personality development, conscientiousness, agreeableness, and emotional stability tend to increase from childhood into late midlife. By contrast, extraversion and openness increase through young adulthood and then show little change through late midlife (Roberts, Walton, & Viechtbauer, 2006). Normative mean-level personality trait change in older adulthood is studied less often. However, what evidence does exist suggests declines in openness and extroversion, continued increases in agreeableness, little change in emotional stability, and declines in conscientiousness (Lucas & Donnellan, 2011).

Paralleling these normative mean-level changes, the cumulative continuity principle of personality trait development proposes that rank-order stability increases in degree through late midlife. Effectively, this means that while individual scores may be increasing on a given trait, those highest in this trait remain highest and those lowest remain lowest (Roberts & DelVecchio, 2000). However, these patterns do not continue into late life. As individuals enter late life, rank-order stability begins to diminish (Lucas & Donnellan, 2011).

As with the majority of developmental processes, normative patterns of trait development are not universal, however. Instead, individual differences in patterns of stability and change prevail throughout the lifespan and variability in patterns of stability and change in individuals may itself be normative. A number of mechanisms support personality trait consistency including genetics, consistent environments, and a variety of person-environment transactions. For example, people often select themselves into environments consistent with their existing personality thus facilitating stability in, or continued development of, personality traits along the same trajectory. That is, a highly extraverted individual may choose a job that involves a good deal of social interaction that will itself maintain or enhance extraversion in that individual (Roberts & Wood, 2006).

One of the defining mechanisms of personality trait maturation in adulthood is the social investment principle which states that individuals who commit to adult social roles that are in keeping with the social clock expectations of their culture tend to follow normative patterns of trait maturation. When an individual acquires and commits to a role, the expectations associated with that role become important to the individual who then begins to act in accordance with these expectations. For example, on entering the corporate 9–5 world, new employees are expected to show up on time wearing clean clothes and behaving in responsible, reliable ways – all core aspects of conscientiousness. As the individual identifies with a new role, these expectations become key parts of personality and are thus reflected in more mature trait ratings. Critical in early and middle adulthood, social investment also helps understand trait maturation in older adult samples, particularly for maintaining and growing conscientiousness. Older adults who are highly invested in social roles continue to increase in conscientiousness, but those who are highly disengaged decline in conscientiousness over time (Lodi-Smith & Roberts, 2012).

The fact that social engagement is a buffer against otherwise normative declines in conscientiousness is particularly compelling in light of the impact of personality traits on physical, cognitive, and psychological health throughout the life span. Personality traits, particularly conscientiousness and emotional stability, are key predictors of healthy aging. For example, both conscientiousness and emotional stability predict longevity, health, and later onset of Alzheimer's. Personality may also be critical for cognitive fitness in late life (Luchetti et al., 2016).

This then raises the obvious question of can an individual change his or her personality? Certainly, evidence suggests that by entering into socially engaging roles, an individual can foster mature personality trait development. There is also some emerging evidence that if people want to change and lay out a clear plan for their personality to change, then their personality will change. Specifically, individuals must (a) want the change, (b) believe the change can happen, and (c) maintain the behaviors associated with the change. Work in this area is new, however, and more research is needed to understand the patterns and mechanisms of directed trait change (Hennecke, Bleidorn, & Denissen, & Wood, 2014).

Although the personality trait model charts changes and stability over time in the components that make up an individual's typical ways of responding to experiences, it does not speak to the issue of self-awareness and how this may change over time. Such self-awareness can include knowledge of the individual's personal attributes including schemas for one's physical appearance, cognitive abilities, social roles, and personality, among other self-ascribed qualities. Relevant to our discussion is the awareness individuals have of their own personality traits. Individuals may be highly introverted, and recognize themselves as such, or they may be highly introverted but believe that they prefer the stimulation of having other people around them.

The identity process model (Whitbourne, 1986; Whitbourne, Sneed, & Skultety, 2002) provides a framework for understanding how individuals both shape and react to changes in these self-schemas over the adult years. Through identity assimilation, individuals interpret their experiences in such a way as to make these interpretations consistent with their existing sense of self. Returning to the case of conscientiousness, the person who is actually low on conscientiousness but has an identity as a highly conscientious person would, through identity assimilation, interpret the experience of being late as reflecting external factors such as traffic or an alarm failing to go off due to a phone's low battery.

The converse process, identity accommodation, occurs when individuals change their self-schemas in response to their experiences. Over repeated instances of being late, as the chronically late "conscientious" types are confronted by friends or supervisors, they may start to bring their identities in line with their experiences. As they enter this process of adaptation, they may undergo a period of self-scrutiny in which they reflect back on times in their life when they blamed others for their lateness or refused to acknowledge it. Eventually, as they start to form a more realistic sense of this aspect of their personality, they will gain insight into their actual level of conscientiousness and their identity will reflect this alteration.

Ideally, individuals maintain a balance between identity assimilation and identity accommodation, but at any one time, one of those processes may predominate. Individuals who now accept the fact that they are not as conscientious as they believed they were are engaging in identity balance and, presumably, are able to take a more realistic view of situations in which they either are, or are not, behaving in a manner consistent with a conscientious personality.

While self-awareness changes through this process, it is likely that individuals who gain insight into their personalities also change in the way they respond to questionnaires measuring Five Factor traits. Once a "7" (the highest possible score) on a conscientiousness item, they may now choose a "4" or "5" instead. Studied over time, then, their actual conscientiousness may seem to change, when in fact what changed was their self-awareness of their personalities. However, their scores may remain unchanged if they use the self-awareness they have gained as a motivation for "change," and they in fact start to appear on time for their obligations.

Changes in identity also expand to a larger range of schema than personality traits. As individuals age, they are increasingly faced with the prospect of looking and behaving in ways that classify them as "old." Given the ageism prevalent in Western society, such realization may come at a price. In fact, however, older adults are able to maintain their self-esteem through a combination of identity assimilation (continuing to deny the reality of age-related changes) and identity accommodation (recognizing that they are aging)

so that they eventually are able to maintain their self-esteem (accepting the fact that they are aging but not feeling threatened) (Sneed & Whitbourne, 2005).

Identity development also occurs in the context of the larger process of ego development, an approach that emphasizes the growth over the individual's life of adaptive abilities within personality. The best-known proponent of the theory of ego development is Erik Erikson, who described eight stages in the growth of the ego, or conscious component of the psyche. Representing a biopsychosocial process, Erikson believed that the ego grows across eight periods in which there is a heightened vulnerability to a combination of physical changes, cognitive and emotional capacity, and social pressures. The phase of identity development peaks in adolescence when individuals are experiencing the process of physical maturation, development of the capacity for abstract thought, and the expectation that they will make commitments in the areas of occupation and ideology.

Once resolved, identity remains a continuing area of development throughout life even as subsequent issues start to emerge, such as the need to find a close romantic partner (intimacy), establish a sense of legacy (generativity), and come to accept the reality and constraints of life and mortality (ego integrity). Although Erikson did not believe that psychosocial issues such as identity are limited to one period of life (cf. Whitbourne, Sneed, & Sayer, 2009), he did maintain that there was a period when individuals are most likely to confront these issues. Similarly, as Erikson charted the matrix of ages for which most psychosocial issues are likely to be confronted, it is also possible for individuals to confront issues in an "off-diagonal" manner. The young infant coping with loss of a parent may be dealing in some way with ego integrity issues; conversely, the older adult who is the victim of elder abuse may be grappling with the "infancy" issue of trust.

Taking the notion that identity development remains a central theme in life one step further, a similar pattern can be seen in the metacognitive process of self-concept clarity. Specifically concerned with an evaluation of the consistency and certainty of the individual's sense of identity over time, cross-sectional evidence suggests that self-concept clarity is most robust in midlife adults relative to young and older adults. In the literature to date, lower levels of self-concept clarity in older adults seem to be contingent on higher levels of health-related role limitations. Indeed, role identity and role transitions appear to be a central part of self-concept clarity. The shifting demographic, physical, and cognitive lives of older adults may present unique challenges to identity-defining roles and thus to overall self-concept clarity. As self-concept clarity is linked to a host of psychological health outcomes, the maintenance and promotion of self-concept clarity in late life is an important concern for future research (Lodi-Smith et al., in press).

People's narrative identity, captured by individual differences in the ways in which individuals tell the general story of their lives and the central experiences of that story, also shifts in older adulthood. The autobiographical memories that define this aspect of personality are subject to positivity bias and heavily grounded in reminiscence. That is, within normative aging trends, older adults tend to remember events from ages 10 to 30, their memories of these events skew toward a positive affective interpretation, and they use memory not only in a way to define personal identity but also to relate to others and to provide guidance to future generations. The more individuals rely on identity assimilation, the more that positivity bias will appear as they shape their memories in terms of their desired self-schemas (Adler et al., 2016).

However, research on how autobiographical memory integrates with narrative identity in late life is still emerging. Central aims for future work in this area will require a look at how older adults differ in their use of the key motivation, affective, and integrative themes of narrative identity as well as how structural elements of narrative identity such as coherence and complexity function in late life relative to in earlier periods of the lifespan. Further, future research will need to develop the extent to which individual differences in narrative processing predict physical, cognitive, and psychological health in late life above and beyond the effects of other personal and situational indicators of aging well. Finally, little is known about how narrative identity is affected by cognitive changes in later life. Future work will help to examine how, as memory for core autobiographical experiences declines, changes occur in narrative identity.

Personality and Longevity

Leslie R. Martin

La Sierra University

Introduction

Personality, our relatively stable individual patterns of behavior, motivation, and thought, is linked to health through multiple pathways. These include personality-related predispositions to engage in (or refrain from) certain health-relevant behaviors (Bogg & Roberts, 2004); personality's influence on social relations (Pierce, Lakey, Sarason, & Sarason, 1987); and personality's association with neuro-immunological activity such as through the hypothalamic-pituitary-adrenal (HPA) axis (Segerstrom, 2000). Although there are many labels that may be applied to personality characteristics, researchers have gravitated toward a theoretical model that defines five broad personality traits that seem to capture the primary ways in which individuals vary (Goldberg, 1993). Each of these traits is comprised of additional, more specific sub-traits or "facets," and the five broad dimensions ("Big Five") are typically labeled: conscientiousness, openness to experience, extraversion, neuroticism, and agreeableness. Since the 1990s, health researchers have been using this Five Factor Model for many (though not all) examinations of personality and health, including longevity.

Because longevity reflects the amalgamation of so many factors, it is perhaps surprising that an abstract thing like personality could predict it in any reliable way. Yet, this is exactly the case – through the pathways already described for linking personality to various aspects of health. The following sections will summarize what we know about how each of the Big Five personality factors relates to longevity.

Conscientiousness

Conscientiousness, a broad trait that includes things like diligence, reliability, and low-impulsivity, is the most clearly protective of the Big Five. A meta-analysis of 20 studies (Kern & Friedman, 2008) showed only positive associations between conscientiousness

and longevity, and the size of the effect appears comparable to the well-established SES-to-mortality association (Roberts, Kuncel, Shiner, Caspi, & Goldberg, 2007).

Conscientiousness is associated with health-relevant behaviors such as diet, exercise, smoking, and alcohol consumption (Bogg & Roberts, 2004) but its link to mortality risk is only partly explained by healthy behaviors (Martin, Friedman, & Schwartz, 2007). Biological pathways, although less clearly understood, also seem relevant – such as the observed relation between a variant gene sequence, lower conscientiousness, and abnormal hypothalamic-pituitary-adrenal (HPA) axis responses (Wand, McCaul, Yang, Reynolds, Gotjen, Lee, & Ali, 2002), and links between low conscientiousness and interleukin-6, an inflammatory marker that predicts mortality (Gruenewald, Seeman, Ryff, Karlamangla, & Singer, 2006).

Some studies, such as this one on interleukin-6, control for health behaviors, suggesting that the planful and organized nature of a conscientious individual may result in better preparedness and therefore less perceived stress during challenging situations. This idea is supported by the finding that conscientious students reported less pressure and fewer hassles over three years (Vollrath, 2000) and meta-analytic findings that people higher on conscientiousness are less likely to cope in negative ways (such as denial or substance use) and more likely to engage in problem-focused coping (Connor-Smith & Flachsbart, 2007).

Openness to Experience

The trait labeled "openness to experience" includes elements such as creativity, flexibility, imagination, and curiosity. Although not as extensively investigated as conscientiousness, openness has been linked to decreased all-cause mortality risk (Iwasa, Masui, Gondo, Inagaki, Kawaai, & Suzuki, 2008) and in particular the facets of cognitive and behavioral flexibility, interest in aesthetics, and curiosity seem relevant. The mechanisms linking openness to longevity are somewhat murky. Reactions to stressors may again be relevant, as people higher in openness have been found to be less reactive when encountering stressors in a laboratory situation (Williams, Rau, Cribbet, & Gunn, 2009). Better maintenance of cognitive functioning may also be relevant (Duberstein, Chapman, Tindle et al., 2011), perhaps enabling individuals to appropriately manage, or even to better avoid, health problems.

Extraversion

As a broad trait, extraversion includes the aspects of sociability, activity, warmth, and generally positive mood. The association between this trait and longevity is mostly, although not entirely, consistent. General extraversion (Iwasa, et al., 2008) and the activity facet (Terracciano, Lockenhoff, Zonderman, Ferrucci, & Costa, 2008) predict decreased all-cause mortality risk, but not all studies find this association (e.g. Weiss, & Costa, 2005).

Dispositional optimism, although not one of the Big Five, deserves mention here as it reflects the tendency to have positive expectations for the future; most researchers would consider it, in Big Five terms, to reflect high extraversion and low neuroticism (discussed in the

next section). Optimism is not always associated with improved longevity (Martin et al., 2002), perhaps because optimists experience greater frustration when things do not go as planned, or remain in stressful situations longer because they expect them to eventually turn out well (Segerstrom, 2006). However, the bulk of the evidence suggests that optimism is protective most of the time and the most likely mechanism explaining this association is adaptive coping (Solberg Nes & Segerstrom, 2006).

Neuroticism

Neuroticism, in the Big Five sense, embodies tendencies toward unstable and negative emotions, including anxiety, hostility, depression, and self-consciousness. Not only are these qualities often linked to poorer health; some long-term studies of neuroticism (e.g. Terracciano et al., 2008) and a meta-analysis of emotional instability (Roberts et al., 2007) show links to increased mortality risk. Other studies, however, fail to confirm this association (e.g. Iwasa et al., 2008) and some find neuroticism to sometimes be protective (e.g. Weiss & Costa, 2005). These wide-ranging results have led to the hypothesis that there may be two forms of neuroticism (Friedman, 2000) – an adaptive form that directs individuals toward health-protective behaviors and an unhealthy type that increases perceived stress and encourages ineffective or even harmful coping strategies.

Agreeableness

The final Big Five trait, agreeableness, includes characteristics such as compassion, trust, altruism, and being easy to get along with. The data do not suggest a strong association between agreeableness and longevity, although there is some evidence of a protective effect (Weiss & Costa, 2005). Other studies find little evidence of an effect (e.g. Iwasa et al., 2008) and it has also been associated with increased mortality risk (Chapman, Fiscella, Kawachi, & Duberstein, 2010). The data on one aspect of (low) agreeableness – interpersonal antagonism – does seem important, especially when combined with anger to yield hostility.

A great deal of research has focused on hostility, and it is generally linked to poorer health outcomes and decreased longevity (e.g. Iribarren, Jacobs, Kiefe et al., 2005) although again, there are some studies that fail to show the link to mortality. When hostility is viewed in terms of its components, most agree that the combination of anger, antagonism, and cynicism is a risk factor, particularly for cardiovascular death (Smith, Glazer, Ruiz, & Gallo, 2004).

Conclusion

In the past four decades, evidence that personality traits are important contributors to longevity has mounted. For some of the Big Five traits (e.g. conscientiousness), the data are fairly clear; but for other traits the evidence is more murky. Ongoing research is focused on identifying the components of broad traits that are more important and the ways in which they interact with other factors to produce unique outcomes across the life span.

Personality and Health

Leslie R. Martin and Chloe R. Maksoudian

La Sierra University

With roots in philosophy and fueled by growing biological sophistication, the idea that the mind or "psyche" can affect the body or "soma" developed into the formally recognized subdiscipline of health psychology in 1978. From Hippocrates forward, the idea of homeostasis – whether of bodily humors or physiological arousal – has been recognized as important, with deviations linked to poor health and disease. Study of the ways in which personality (relatively consistent individual differences in patterns of behaviors, attitudes, and motivations; McCrae & John, 1992) is related to health and illness is one major aim of health psychology.

Prominent among modern typologies relating personality to health was the Type A behavior pattern. In the 1950s, cardiologists identified work-driven, impatient, tense individuals whose characteristic styles of interacting with the world put stress on their nervous systems and increased their risk of cardiovascular disease (Chesney & Rosenman, 1985). Those without these characteristics were labeled "Type B" and others later added additional categories.

Over time, typological conceptualizations diminished in popularity and a view of traits as existing on a continuum with many interacting elements became widely accepted. Hans Eysenck (1967) was one of the first to link personality traits to underlying biological mechanisms such as baseline cortical arousal, proposing a three-factor model of personality including introversion/extroversion, neuroticism, and psychoticism; this was an important step for the field. Another key breakthrough was the identification of the "disease-prone personality." In an effort to more completely capture what was known about personality-health relationships, Friedman and Booth-Kewley (1987) conducted a meta-analysis of the associations between emotional components of personality and various chronic diseases. Rather than disease-specific links, however, they identified the more general "disease-prone personality" that places individuals at risk for a variety of negative health outcomes; this discovery highlighted the importance of measuring multiple personality factors, health outcomes, and other relevant variables in studies of personality and health and reminded researchers that simple associations are seldom very useful.

Most contemporary personality psychologists now recognize the Five Factor Model (FFM), a lexically based and universally identifiable set of five higher-order dimensions – extraversion, neuroticism, agreeableness, conscientiousness, and openness – each including multiple lower-order facets (McCrae & John, 1992; John, Naumann, & Soto, 2008). The identified relationships between these constructs and physical health vary, and not all factors have been equally studied. Also, the ways in which these personality factors and health outcomes are related are complex, including behavioral pathways, habitual reactions to stressors, and genetic predispositions, as well as other health-relevant elements like symptom perceptions and reporting. Because multiple pathways function at the same time, health is somewhat subjective, and assessment is challenging, the ideal approach is to study personality–health links from a lifespan perspective. The extant literature contains many cross-sectional and some longitudinal studies and we now examination the relationships, demonstrated in both types of studies, between FFM traits and health.

Of the Big Five, openness to experience (which includes elements of imagination, creativity, intellect, and wide-ranging interests; Caspi, Roberts, & Shiner, 2005) has probably received the least research attention from health psychologists. Studies have tended to focus on one or more openness facets, and findings have been inconsistent. For example, individuals high on "action," possibly because they readily engage in new experiences, tend to have more frequent experiences of positive emotion (Carrillo, Rojo, Sánchez-Bernardos, & Avia, 2001); and many behaviors and positive emotions associated with openness appear to serve as buffers against depression (Salovey, Rothman, Detweiler, & Steward, 2000) which links, in turn, to decreased mortality risk. Additionally, data suggest that individuals higher in openness exhibit lower levels of reactivity when encountering laboratory stressors (Williams, Rau, Cribbet, & Gunn, 2009). These same tendencies toward engagement, however, have sometimes been linked to poor health behaviors (such as substance abuse) as a means of experience-seeking (Booth-Kewley & Vickers, 1994), and similar contradictory results have been found for other openness facets.

In contrast to the relative paucity of data on openness-health links, neuroticism has received a great deal of attention from health psychologists – and, although the data are more consistent, there are still contradictions. Individuals high on neuroticism experience more frequent and extreme negative feelings such as anxiety and tension (John, Naumann, & Soto, 2008), psychosomatic symptoms (Costa & McCrae, 1987), and to be discouraged by symptoms, leading to avoidance behaviors that may keep them from seeking medical treatment (Goubert, Crombez, & Van Damme, 2004). There is also substantial evidence suggesting links between neuroticism and specific physical health problems, such as Type 1 diabetes and cardiovascular disease (Smith & MacKenzie, 2006). Some suggest that the use of subjective methods may contribute to overidentification of neuroticism with poor health – indeed, the strongest health links are seen when neuroticism is examined in the context of subjective well-being (Costa & McCrae, 1987) and although most research links neuroticism to some negative health indicator, this is not true in every case. For example, neuroticism was found to be significantly protective from mortality risk for men, following the major stressor of widowhood (Taga, Friedman, & Martin, 2009). Friedman (2000) suggests that neuroticism may take two forms: one reflecting anxiety, pessimism, and depression and the other being more positive in nature, prompting vigilance and proactive engagement to alleviate symptoms and promote health.

Conscientiousness, which describes an individual's tendency toward competence, order, achievement, and caution (McCrae & John, 1992), has demonstrated consistent links with health. In 1993 conscientiousness was identified as a predictor of lifespan mortality risk (Friedman et al., 1993) and other studies are consistent with these findings, demonstrating clear, positive relationships between conscientiousness and health (Kern & Friedman, 2008). The most obvious link between conscientiousness and health is behavioral – conscientious people tend to avoid risks and engage in more protective behaviors (Bogg & Roberts, 2004), and to respond to stressors in positive and productive ways (Connor-Smith & Flachsbart, 2007). Conscientious people also tend to invest in social relationships (e.g. communities, marriages, and families), which are all associated with better health (Friedman et al., 2010).

Agreeableness, the tendency to be compliant, altruistic, and easy to get along with, has often been examined in terms of its counterpoint – hostility. Hostility reflects neuroticism (previously discussed) and low agreeableness. It predisposes one to chronic stress and is also related to poorer health behaviors, such as smoking and alcohol use, all of which are relevant to subsequent disease (Bunde & Suls, 2006). Conversely, individuals higher on agreeableness work better with others and often have healthier social relationships (John, Naumann, & Soto, 2008); they cope more effectively with stress, and use more social support (Connor-Smith & Flachsbart, 2007). Not surprisingly, agreeableness predicts subjective measures of health, but is less consistent when it comes to objective indicators (Roberts et al., 2007).

Finally, we turn to extraversion – a trait including assertiveness, gregariousness, and warmth – which has been inconsistently linked with health (Roberts et al., 2007). The facet of extraversion being examined, as well as its combination with other facets and traits, seems particularly important. For example, it is suggested that more assertive individuals may respond differently to stress, be more proactive in preventative health care, and be more engaged in their own recovery processes (Howell, Kern, & Lyubomirsky, 2007); sociability is associated with positive engagements (Carver & Connor-Smith, 2010); and social individuals may interpret situations as less stressful and have more resources with which to counteract stress (Fredrickson, 2001). At the same time, extroversion may encourage some to enter situations that promote unhealthy habits (Raynor & Levine, 2009).

It is clear that modern scientific conceptions of health must include psychological and social aspects – one useful way of framing these is the personality perspective. As is seen throughout this piece, the associations are complex and interactive – there are no simple associations between personality and health.

Personality and Well-being

Jake Womick and Laura A. King

University of Missouri

Observing newborns in a hospital nursery, it is clear that some of the babies are happier than others. This noticeable feature of any group of people persists throughout life. Largely independent of specific circumstances, some people are happier, less unhappy, and more satisfied with their lives than others are. At least part of the explanation for the stability of well-being lies in reliable individual differences or personality. This entry reviews the substantial relationship between personality traits and well-being, summarizing the ways psychologists have tried to understand this relationship, moving from a focus on personality leading to (or influencing) well-being to a more nuanced and increasingly bidirectional perspective.

History, Measurement, and Associations

Both well-being and personality have been of interest to humanity for millennia: Hippocrates attached the bodily humors not only to emotional qualities (e.g. carefree, optimistic) but to personality traits (e.g. lively, talkative). Still, the emergence of the current vibrant study of well-being and personality can be traced to less than 40 years ago. The science of well-being gained its surest footing in the 1980s when, in a landmark article, Diener (1984) defined subjective well-being (now often termed *hedonic* well-being because of its emphasis on subjective feelings) as comprising the amount of positive affect (PA) and negative affect (NA) a person experiences along with an evaluative judgment of life satisfaction. Similarly, although factor analyses had long been applied to personality traits, it was in the 1980s that the dominant trait approach to personality truly gained traction. Five broad traits were identified (e.g. Costa & McCrae, 1988), including neuroticism (sometimes named for its opposite, emotional stability), extraversion (outgoing, sociable), openness to experience (unconventional, creative, open-minded, interested cultural and intellectual pursuits), agreeableness (kind, nice, gentle), and conscientiousness (reliable,

dependable, persistent, orderly). Both well-being and personality traits are typically measured using face valid self-report scales, allowing these variables to be measured in large, representative samples. As such, conclusions about the associations between well-being and personality have been tested rigorously using large cross-sectional and, at times, longitudinal datasets.

Research strongly indicates that personality traits are one of the most robust concurrent predictors of well-being. Meta-analyses (DeNeve & Cooper, 1998; Steel, Schmidt, & Schultz, 2008) strongly support the following associations between personality and well-being. Neuroticism is negatively correlated with well-being: it shares negative relations with PA and life satisfaction and a positive association with NA. Extraversion is positively correlated with well-being (especially PA). Agreeableness and conscientiousness also share positive associations with well-being. Longitudinal evidence extends some of these associations in predictable directions. Extraversion predicts greater PA and neuroticism predicts greater NA and lower life satisfaction, prospectively. Agreeableness predicts increases in life satisfaction over time (e.g. Specht, Egloff, & Schmukle, 2013).

What explains these consistent, robust associations? The way scientists have sought to answer this question has changed as research has accumulated. Early attempts to explain the association between personality and well-being were often framed in terms of how personality might influence well-being, but more recently alternatives to this unidirectional approach have become more commonly considered. Research on the very strong association between extraversion and PA exemplifies this movement.

The Example of Extraversion

Scholars have tested a variety of highly intuitive and reasonable mediators for the association between extraversion and PA. For example, one explanation for how extraversion might influence well-being was through social activities. Such activities are a robust predictor of positive mood. Yet this sociability explanation cannot account for the fact that extraverts are happier than introverts even when they are alone (Lucas & Baird, 2004). Another possibility was that extraversion involves a susceptibility to PA, suggesting that extraverts are simply more likely to enjoy a large boost of positive mood when good things happen. Yet, in an exhaustive series of studies, Lucas and Baird (2004) found that extraverts were not only happier than introverts following positive mood inductions but also in control conditions. Research, then, points to the conclusion that high levels of PA may be "baked into" extraversion – that these variables share more than is implied in the search for the *influence of* extraversion on well-being.

Similarly, personality traits more generally predict well-being over and above variables thought to be important for a happy and satisfying life (income, marital status, employment, health, etc.) (Lucas & Diener, 2015). Research has also examined whether traits moderate the effects of life events on well-being but evidence for such effects has been inconclusive and weak. On a general level, personality shares a strong relationship to well-being that is not mediated by contextual factors. Why might this be the case?

Temperament, Genes, and Development

Consider again those infants in the hospital nursery. Temperamental differences that exist in infancy may be the building blocks of both later personality traits and dispositional well-being, suggesting that Hippocrates' ancient linking of personality traits with affective dispositions makes sense. Thinking about it in this way suggests that traits do not simply *lead to* well-being differences, but rather they *reflect* differences in temperament, genetic, and neurobiological systems that inform both personality and well-being.

Individual differences in personality traits and well-being are substantially explained by genetic differences. Moreover, an analysis of 973 twin pairs (Weiss, Bates, & Luciano, 2008) revealed that genetic sources of variation in personality and well-being overlapped, especially for extraversion, neuroticism, and conscientiousness. These analyses imply that the association between personality and well-being is, at least in part, explained by a shared (genetic) third variable.

Bear in mind that no amount of heritability suggests that environmental factors do not matter to any characteristic, nor does a genetic role in these dispositions suggest that they are unchangeable. This analysis does suggest that personality and well-being are likely to be strongly related even as they may become increasingly differentiated with age and maturity. Indeed, over time we can think of them each influencing and being influenced by the other.

The closely intertwined relationship of personality and well-being is demonstrated in their relations over time. Each of these characteristics is relatively stable but they each show normative changes as well. For personality, trait changes over the life course show increases in agreeableness and conscientiousness and decreases in neuroticism – trait changes that appear to reflect maturation or personality development (Roberts, Walton, & Viechtbauer, 2006). For well-being, research shows a normative increase of PA and decrease in NA with age. Longitudinal studies demonstrate how levels of each of these classes of variables influences the normative changes of the other.

The strong concurrent associations between personality and well-being set a context similar to ceiling effects (Hill, Mroczek, & Young, 2014). For example, high extraversion sets a high bar for positive affect and therefore extraversion is likely to predict *less change* in PA over time. Rather, extraversion predicts stable, high levels of PA with age, and neuroticism predicts less decline in NA with age (Charles, Reynolds, & Gatz, 2001). Such results demonstrate how personality contextualizes age-related well-being changes and show personality as a force for stability in well-being.

The Pursuit of Happiness and Personality Development

Even longitudinal studies are correlational and fully understanding of the association between personality and well-being requires consideration of the pathway *from* well-being *to* personality changes. Well-being may influence personality because it provides a powerful incentive to engage in behaviors that lead to pleasant feelings. An individual might change his or her typical behavior to gain happiness. The resulting affect might reinforce that behavior. Behavioral changes might become routinized such that they become part of

the person's typical repertoire, a part of his or her personality. Is there any evidence for well-being predicting trait changes?

Two large-scale longitudinal studies have demonstrated that high stable levels of well-being systematically predict increases in conscientiousness and agreeableness, and decreases in neuroticism (Soto, 2015; Specht, Egloff, & Schmukle, 2013), a pattern of trait changes that is widely considered to represent personality development. Thus, high well-being appears to foster behaviors and feelings that contribute to increases in mature personality traits.

Alternative Approaches to Personality and Well-being

There are other ways of conceiving of personality and well-being. Personality encompasses not only traits but a host of other variables, including motives. Motivational pursuits representing intrinsic (vs. extrinsic values) are positively predictive of well-being (Sheldon & Krieger, 2014). Other personality constructs (e.g. beliefs and expectancies), as well as lower-level trait facets, are related to well-being in very intuitive ways. It is likely that as research continues to explore the association between personality and well-being, each class of variables will be studied in ever more fine grained detail. In addition, subjective well-being does not subsume all of the ways well-being has been conceptualized. For example, "flourishing" is an approach to well-being that balances both subjective well-being and indicators of social well-being. Flourishing is less strongly related to traits and may be less genetically related to them as well (Keyes, et al., 2015).

Self-Regulation and the Changing State of Well-being

Consider that two components of well-being, PA and NA, include state-like aspects. That PA and NA are responsive to life events and circumstances is crucial to their role in self-regulation. Moods tell us how things are going and spur us to take action when the news is not good. If well-being were perfectly stable, self-regulation of goal-directed action could not occur. Consider, as well, that recent research (using longitudinal datasets) has documented long-term changes in well-being (typically declines) spurred by life events (Luhmann, Hofmann, Eid, & Lucas, 2012). Such results suggest that some events are not so easily adapted to as was previously thought. Thus, although personality supports the stability of well-being, it is not immune to changes fostered by life events. Happiness is not wholly a "personality-thing." However, the two psychological characteristics are sufficiently linked that one ought not to be considered without the other. Personality and well-being are strongly connected and best understood when considered together.

Self-Healing and Disease-Prone Personalities

Dietlinde Heilmayr[1] and Howard S. Friedman[2]

[1] *Moravian College*
[2] *University of California, Riverside*

Introduction

Since the turn of the twentieth century, the leading causes of death have shifted from infectious diseases like tuberculosis to chronic diseases like cardiovascular disease, cancer, and obstructive pulmonary disease. The biomedical model of health – whereby the absence of disease is equated with health – successfully fostered the dramatic decreases in illness and death from infectious diseases through major improvements in sanitation, nutrition, inoculations, and antimicrobial medications. Modern societies are no longer devastated by the scourges of tuberculosis, enteritis/diarrhea, and diphtheria; these were the clear triumphs of the biomedical model. The leading causes of impairment and premature death in modern society – chronic diseases that develop slowly over long time periods without an infectious microorganism – are heavily influenced through behavioral pathways, and are not as responsive to the previously successful tactics derived from the biomedical model. Engel's biopsychosocial model (1977) jointly considers biological, psychological, and social characteristics to determine the cause, development, and treatment of disease, as well as the promotion of wellness. The shift from the *biomedical* to the *biopsychosocial* model of health introduces a new way of thinking: instead of health being the default, health becomes a pattern of wellness-promoting thoughts, behaviors, and emotions that lead to healthy psychosocial pathways.

Research psychologists have elucidated many core links between personality and health, providing scientific insight into the questions of *who* gets sick and who stays well. Much of this work initially faltered as researchers searched for narrow personality correlates of single diseases – for example, "hurry-sickness" and heart disease. There are two substantial flaws with such an approach. First, personality traits do not exist in a vacuum, but rather accompany other traits and unfold in situations and contexts. Thus, focus should be on how multiple personality characteristics play out across different situations throughout the lifespan. Second, instead of considering individual disease outcomes, it is much more

sensible and heuristic to consider broader outcomes: for example, although a certain trait or behavior pattern may predict decreased odds of heart disease, it is likely not a healthy personality if the individuals succumb to cancer at an early age instead. Indeed, ideas of a coronary-prone personality stumbled, with insufficient attention both to the construct itself and the broader health outcomes. In other words, longitudinal studies with multiple predictors and multiple outcomes are necessary when seeking to understand the interactional patterns that act on health across the years.

Studies focused on such broad, long-term health been encouraged by Howard S. Friedman's concepts of the *disease-prone* and *self-healing personalities* (Friedman & Booth-Kewley, 1987; Friedman, 1991). These pathways toward disease or health emphasize an individual's fit with the environment, consider both traits and situations, and are considered to be self-reinforcing through the processes of situation selection and evocation. Some individuals create better matches and healthier environments for themselves over time while others head from crisis to crisis. These pathways are characterized by distinct ways of thinking, feeling, and behaving.

Disease-Prone Personality

Some individuals find themselves, or place themselves, in environments that are a poor match for their biopsychosocial needs. That is to say, an individual's environment (e.g. job, social environment, cultural context) is not supportive of or conducive to the individual's personal needs, goals, or values. This kind of mismatch may lead to disease through inter-related combinations of: unhealthy *behaviors* such as substance abuse; chronic negative *emotions* that disrupt social life; and chronic *physiological* disturbances such as changes in metabolism, sleep, immune function, and breathing patterns.

Personality leads people to encounter better or worse environments and to construe events in a certain light (Friedman, 2007). First, although some events, such as being struck by lightning, seem random, not everyone stays outside during storms, drives recklessly without a seatbelt, bounces from one bad marriage to another, or wanders dark alleys alone. Impulsive, lonely, hostile, insensitive, depressed or otherwise immature people are more likely to put themselves into risky situations and objectively face more stress (Friedman & Kern, 2014). Second, disease-prone individuals are less likely to find the positive that might emerge from stress or challenge, thus missing out on opportunities for growth or meaning-making. Likewise, an individual with a disease-prone personality is more likely to cope with chronic stress by using drugs, drinking alcohol, over-eating unhealthy foods, and engaging in promiscuous sexual relationships – behaviors that promote disease and predict a shortened lifespan.

Individuals with a disease-prone personality may be dispositionally hostile. While some are easily frustrated and excitable, others are more cynical and alienated (Friedman, 1998). Though the majority of studies focus on hostility's association with cardiovascular disease (via autonomic nervous system hyper-reactivity), there is evidence that hostility is predictive of other diseases and all-cause mortality as well (Barefoot & Williams, 2010). Chronic antagonistic behavior is frequently associated with drug or alcohol abuse, violence, and risk-taking. Moreover, hostile proclivities generate interpersonal disputes and disrupt social support networks that are important to good health in many ways.

Disease-prone individuals may also be repressed – unassertive and compliant, lacking the self-disclosure that can promote health (Pennebaker & Seagal, 1999). This pathway is also likely related to feelings of control and self-regulation. For example, when individuals write about traumatic events, they begin to make sense of those events, and gain a sense of coherence and purpose. Repression can prevent such sense-making, which in turn may both evoke physiological responses and disrupt social relations. It may be, however, that repression is often a red herring for chronic stressful challenge; the underlying issue is the severe emotional imbalance in the first place (Friedman, 1998).

Depression is the most controversial and misunderstood relation between personality and disease. Depression is indeed associated with chronically elevated levels of the stress hormone cortisol and with poor health behaviors such as irregular sleeping and eating, impaired social relations, and substance abuse. But the causal pathways between depression and health are undoubtedly multifaceted and multidirectional. Depression can be the *result* of as well as a contributor to illness. Depression may also be the result of third variables – such as chronic physical inactivity – that affects both personality and disease. Much evidence suggests that treating patients who have cardiovascular disease for depression does not necessarily reduce the overall risk of dying (Friedman & Kern, 2014; Rutledge, Redwine, Linke, & Mills, 2013). Thus, depression should be considered an important part of a complex web of associations rather than as a direct cause of disease (Friedman, 2007). The role of depression cannot be understood without tracking life experiences across the long term, again highlighting the importance of life-span studies focusing on all-cause mortality (Friedman & Kern, 2014; Friedman & Martin, 2011).

Self-Healing Personality

Individuals with self-healing personalities are emotionally balanced, secure, enthusiastic, and constructive. They are more likely to live long, healthy lives. Some are especially alert, socially responsive, and energetic, while others are especially calm and conscientious. In both cases, good mental health promotes good physical health – a self-sustaining path that unfolds across time (Friedman, 1991). Yet, despite pop culture health tips, endless lists of "do this" and "don't do that" do little to increase health and longevity. Instead of quick tips and tricks, promoting health and longevity depends on mature lifestyles. People with the self-healing personality live such wellness-promoting lives through creating a virtuous circle of thriving.

Individuals who are self-healing are likely to self-select (put themselves) into suitable environments. This is not to say that they avoid challenge. Indeed, many such people select demanding jobs or hobbies, but the challenge of these experiences constitute healthy stimulation. Instead of being interpreted as threats, challenges are viewed as exciting opportunities. Not only do individuals with the self-healing personality have a healthy interpretation of challenge, but they also develop the social support to help them surmount the challenge. For instance, a healthy work environment can be highly challenging, but also provide the individual with social value, and the resources and control to complete the job. Individuals who advance in such demanding, challenging jobs or tasks tend to thrive and live longer (Friedman & Martin, 2011).

A sense of purpose can be important to self-healing individuals fulfilling commitments in the face of challenge. Rather than being blindly optimistic, self-healing individuals gain a sense of meaning from persevering toward their goals. These goals are often powerful and meaningful in their own right, and may include issues of beauty, justice, and understanding. This perspective allows them to adopt valued, meaningful pursuits though abstract goals (Maslow, 1943). Becoming mature or self-actualized involves having a growth orientation that supports working to realize and fulfill one's potential. Self-healing individuals have such a mature growth orientation – marked by spontaneity, creativity, playfulness, and problem-solving ability – which keeps them motivated in working toward their goals (Csikszentmihalyi, 1996; Friedman, 1991; Maddi, 2016).

Self-healing individuals often help others thrive. Health resides within a social context, and by helping others, self-healing individuals promote positive social relationships. Having a reliable social network means having better sources of information, receiving more help, and more advice support in times of need. Such individuals have people they care about, and who care about them. Self-healing individuals are likely to have hobbies and habits that involve positive social interactions; these social interactions reinforce their active, engaged, and healthy lifestyle, maintaining a healthy trajectory (Suls & Rothman, 2004).

Finally, selection into healthy environments, including evocation of ties with healthy others, helps self-healing individuals to maintain homeostasis. The concept of homeostasis, developed by physiologists Claude Bernard and Walter Cannon, involves internal equilibrium – keeping cells and organs healthy to keep an individual healthy. It is not that self-healing individuals do not experience stress and significant physiological arousal, but they are able to return to homeostasis relatively quickly. In other words, self-healing personalities are able to regulate their reactions, keeping them on a healthy pathway toward long life, even in times of challenge.

Applying the Self-Healing Personality

The constellations of biopsychosocial patterns and responses of the self-healing personality can vary from person to person. Simple or generic health advice is not appropriate for everyone. The idea that solutions must be tailored to individual needs seems obvious, but is often ignored (Friedman, 1998).

When we reflect on common advice, we can see where people are often led astray. For instance, striving for early retirement or forcing more beach vacations to get away from "stress" is not healthy for most individuals. In fact, for people who find fulfillment, a social network, and satisfaction from work (often because of its challenges and not in spite of them), retirement may be unhealthy. Rechanneling or redressing truly unhealthy tendencies – such as aggression and impulsivity – is more effective for health promotion than adopting the common lore that everyone should relax, have a drink, and be happy.

Shifting onto a self-healing trajectory usually involves slowly changing habits and altering certain social environments. When individuals adopt healthier behaviors and healthier environments (especially including healthier social groups), their personalities often follow – becoming less hostile and more prudent, for instance. Individuals who shift onto this pathway will begin to seek out and find themselves in environments and situations that

promote positive and productive lives in their communities – be it team sports, prosocial religious involvement, or mature leadership at work, for example.

There is no one specific activity or routine that will shift an individual onto a healthy pathway toward a self-healing personality, but by engaging in activities that incorporate these goals, individuals increase the odds of a virtuous cycle of good health.

Individual Differences in Coping with Stress

Katharine R. Parkes[1] and Emily L. Hughes[2]

[1] *University of Oxford*
[2] *Independent consultant/researcher*

Introduction

To understand individual differences in coping, it is necessary first to define the concept of stress. From a psychological viewpoint, stress occurs when an individual confronts a situation that is perceived as taxing or exceeding their capacity to adapt, and as threatening to their well-being. Thus, stress can be viewed as resulting from a specific type of person-environment interaction. The experience of stress may involve *threat* (anticipated future occurrence of adverse event), *harm* (the perception that adverse consequences already exist), or *loss* (the perception that something desired has been taken away). Within this framework, coping includes all efforts, both behavioral and psychological, to master, tolerate, reduce, or minimize stressful experiences and associated distress, irrespective of whether the strategies used are effective. More briefly, coping has been defined as "all efforts to manage, regardless of outcome" (Lazarus & Folkman, 1984, p. 178).

Much academic discussion has focused on the issue of whether coping should be regarded as a relatively stable dispositional characteristic or as a flexible response to stress primarily determined by situational factors. Richard Lazarus's influential book *Psychological Stress and the Coping Process* (1966) argued that, rather than focusing solely on either stable coping traits or situational characteristics, research into coping should seek to understand the complex dynamic processes involved in managing specific stressful episodes. The theoretical approach of Lazarus and his colleagues placed major emphasis on the role of "cognitive appraisal" which refers to the individual's perceptions and judgments about the nature and significance of a specific stressful transaction (primary appraisal), and the resources available for managing it (secondary appraisal).

In this transactional model, as a stressful episode unfolds over time, the interplay between primary and secondary appraisals influences the nature of the coping strategies adopted, and immediate and longer-term outcomes. Transactional models make a valuable contribution to understanding coping processes, but the complex mechanisms

of reciprocal causation among appraisal, reappraisal, coping, and affective responses are difficult to address empirically; consequently, many studies adopt less complex structural approaches. These models recognize that both consistency (as reflected in dispositional models) and flexibility (as reflected in situational and environmental influences), and possible interactions between these factors, play important roles in determining how individuals manage stressful situations (Parkes, 1986). Within this structural framework, the present entry focuses primarily on individual differences in coping, viewed from a dispositional perspective as relatively stable and consistent patterns of cognitive and behavioral responses to stress, although situational factors are also considered.

The Nature and Assessment of Coping

The earlier literature identified two forms of coping, problem-focused and emotion-focused. Problem-focused coping is aimed at removing, reducing or avoiding the *source* of stress; in contrast, emotion-focused coping seeks to *minimize the distress* associated with the stressor. In most stressful episodes, however, both forms of coping are used in combination; thus, they can be regarded as complementary, each facilitating the other, rather than independent. A more recent approach distinguishes between engagement (or approach) coping and disengagement (or avoidance) coping. Engagement coping refers to strategies directed toward managing the stressor or related emotions, while disengagement coping seeks to avoid the threat or related emotions. Thus, engagement coping includes problem-focused strategies and some forms of emotion-focused coping (e.g. seeking support, acceptance, and cognitive restructuring), while disengagement coping typically involves avoidance, distraction, wishful thinking, and denial, which function to reduce or escape distress but do not change the stressor itself.

Researchers typically use inventories of coping strategies to assess how individuals attempt to cope with stress. Among the first of such scales, the "Ways of Coping" checklist, was developed to assess problem-focused and emotion-focused coping responses. This scale was widely used and subsequently led to the development of several more sophisticated measures with specific sub-scales. However, certain broad categories of coping (e.g. problem-focused strategies, positive reappraisal, seeking support, acceptance/resignation, avoidance, expressing emotions) are common to most coping scales in current use, e.g. the COPE scale.

Coping inventories can be used in several different ways to assess individual coping behaviors. First, respondents may be asked to report in general terms how likely they would be to use each of the strategies indicated in response to stressful circumstances. This method seeks information about an individual's typical pattern of coping strategies, irrespective of situational context; it reflects a *dispositional* or *trait* approach in which coping is regarded as relatively stable over time and consistent across situations. Alternatively, individuals may be asked to describe a recent stressful episode, and report the strategies employed on that occasion. These *situational* scores may be treated as samples of behavior reflecting an individual's general coping traits, or used to examine relations between appraisals, coping strategies, and emotional responses in specific episodes. Reflecting these two possible uses, some coping inventories (e.g. the COPE scale) have been published in

two versions, dispositional and situational. One advantage of situational methods is that coping strategies are more likely to be reliably reported if they relate to a specific stressful episode rather than an abstract context. However, it should be noted that coping inventories can only assess cognitive and behavioral coping attempts about which individuals are consciously aware, and are willing to report; unconscious defense mechanisms are necessarily excluded.

Personality Characteristics and Coping

Personality plays a role at several different points in the coping process; thus, the *types of stressors* encountered by an individual, the *frequency of exposure*, the *appraisal* of stressors, and the c*oping responses* adopted are all influenced by personality characteristics. In the present context, associations between personality and coping (considered as a relatively stable pattern of cognitive and behavioral responses to stress) are of particular interest. Two different approaches to studying these associations can be distinguished (Watson & Hubbard, 1996).

1. Coping responses can be examined in relation to personality models that seek to represent a comprehensive taxonomy of dispositional characteristics. For instance, the "Big Five" model incorporates five orthogonal "super-factors" (neuroticism, extraversion, conscientiousness, agreeableness, and openness) which represent broad, general dimensions of personality. Coping traits show specific patterns of relationships with these five dimensions. In particular, neuroticism plays an important role in influencing experiences of stress and associated coping responses. Individuals high in neuroticism typically report high levels of distress, which suggests that their coping attempts are generally inadequate. Consistent with this view, research evidence shows that neuroticism is associated with greater use of potentially less effective emotion-focused coping responses, including disengagement, avoidance, self-blame, wishful thinking and withdrawal, and with lesser use of problem-focused coping, positive reappraisal, and support-seeking.

   In contrast, extraversion is associated with positive affect and well-being, and with active forms of coping, including problem-focused strategies, positive reappraisal, and engagement coping. Conscientiousness also predicts coping responses, specifically, problem-solving, positive reappraisal, cognitive restructuring, and other forms of engagement coping. Relatively few studies have examined coping in the context of openness and agreeableness but the available evidence suggests that these traits are not strongly related to coping. More recently, researchers have begun to consider how combinations of personality characteristics relate to coping traits. For instance, individuals low in neuroticism and high in conscientiousness and/or extraversion tend to use more effective coping strategies, to be less vulnerable to stress, and to have better physical health (Grant & Langan-Fox, 2006).

2. Alternatively, studies of personality and coping may focus on one or more personality characteristics (chosen for their potential relevance to the context concerned) and examine their associations with specific forms of coping. Some such studies also

include situational appraisals, and possible interactions between personality and situation, as predictors of coping. For instance, optimism is associated with the use of active problem-focused coping and planning in managing stressful events, while pessimists are more likely to disengage from the situation, and to use denial and distraction to avoid having to confront the stressful event (Carver, Scheier, & Segerstrom, 2010). However, the relationship between optimism and problem-focused coping is stronger in situations perceived as controllable; in uncontrollable situations optimists report greater use of positive re-interpretation and attempts to accept the reality of the situation. Thus, optimists appear more able than pessimists to adapt their coping patterns to their situational appraisals.

Coping in a Real-World Context

Theoretical models and associated research have greatly enhanced understanding of the psychological processes involved in stress and coping. However, the relevance of the topic extends far beyond the confines of academic research. Thus, minor day-to-day stressors (e.g. work and family hassles, time pressures, loss or theft of possessions, and interpersonal problems) and, less frequently, major life events (such as death of a close relative or friend, marital break-up, unemployment, or serious illness) impact on everyone's lives. From a wider perspective, natural and man-made disasters (e.g. earthquakes, floods, explosions, terrorist acts) are sources of severe stress with adverse effects on the health and well-being of individuals, communities and nations. In recent years, researchers have sought to understand how coping can play a role in reducing distress and maintaining well-being in these real-world situations.

For instance, among individuals who experienced job loss, coping resources (such as self-esteem and social support), and the use of problem-focused (rather than emotion-focused) coping were found to mitigate psychological distress, and predict greater likelihood of re-employment at follow-up (Solove, Fisher, & Kraiger, 2015). Adaptation to cancer also illustrates the significant impact of appraisal and coping. Thus, in a meta-analysis, Kvillemo and Bränström (2014) found that acceptance and positive reappraisal strategies were positively related to well-being, while disengagement and avoidance were negative predictors, although the effectiveness of different strategies depended on the nature and time course of treatment. Studies such as these can potentially lead to the development of intervention methods to enhance the effectiveness of coping among vulnerable individuals, and/or those who have been exposed to severe psychological trauma. However, a wide gap exists between research findings and clinical practice (de Ridder & Schreurs, 2001); the development of intervention methods has lagged behind academic research.

Much remains to be done to understand the roles of appraisal and coping in relation to the nature and severity of stressful events. There is a need for more prospective research, for greater attention to cultural, situational, and environmental aspects of coping, and for identifying the effectiveness of specific coping responses across the time course of stressful events. Nonetheless, as Folkman and Moskowitz (2004) point out, despite its inherent complexities, the research area holds great promise for explaining who thrives under stress and who does not, and for designing interventions to help people better handle both acute and chronic stress.

Type A/B Personalities

Arlin James Benjamin, Jr.

University of Arkansas–Fort Smith

Introduction

The Type A/B Behavior Pattern construct has evolved considerably in both definition and importance since it was first introduced by cardiologists Friedman and Rosenman (1959). This chapter will provide a brief overview of the Type A/B construct, as well as its measurement. In addition, this chapter will examine changes in our understanding of the relationship between Type A/B Behavior Pattern and its hypothetical impact on health outcomes, such as cardiovascular heart disease and life expectancy based on research conducted across samples representing multiple nationalities and cultures. Since individuals identified as Type A are theoretically expected to be vulnerable to stressors, this entry will summarize some of the available research on the predictive or interactive relationship between Type A/B Behavior Pattern, situational stressors, and behavioral outcomes, such as aggression.

Type A/B Theoretical Construct

The Type A Behavior Pattern was initially characterized as a behavioral pattern comprising three primary qualities: extreme competitiveness, leading to high achievement motivation and leading to vulnerability to stressors; a strong sense of time urgency, leading Type A individuals to be easily frustrated and impatient; and free-floating hostility, leading Type A individuals to be easily angered and provoked (Friedman & Rosenman, 1974). These three qualities were contrasted with the considerably more relaxed Type B pattern, which represents the opposite end of the spectrum of the Type A personality dimension. Although initially defined in terms of behavioral outcomes, subsequent theorists defined the Type A pattern in terms of motivation, such as by a drive toward self-control and mastery over the environment, self-knowledge, or self-esteem maintenance (see Contrada, Cather, & O'Leary, 1999, for details).

Measurement of Type A/B Behavior Pattern

The Type A/B Behavior Pattern is measured either through a structured interview (Friedman & Rosenman, 1959), or more typically using self-report personality inventories, such as the Jenkins Activity Scale (Jenkins, Zyzanksi, & Rosenman, 1979), the Framingham Type A Scale (Haynes, Levine, Scotch, Feinleib, & Kannel, 1978), or the Bortner Rating Scale (Bortner, 1969). Researchers have generally noticed that the internal consistency figures for self-report inventories of the Type A construct appear to be generally low to moderate regardless of the inventory (e.g. Šmigelskas, Žemaitienė, Julkunen, & Kauhanen, 2015).

Type A/B Behavior Pattern and Physical Health Outcomes

Initial research indicated a significant relationship between Type A and coronary heart disease, and the earliest meta-analysis appeared to confirm a strong and significant positive relationship between Type A and coronary heart disease (Booth-Kewley & Friedman, 1987). However, subsequent meta-analyses suggested the relationship between Type A and coronary heart disease was considerably weaker (e.g. Miller, Turner, Guijarro, & Haller, 1996; Myrtek, 2001). According to Miller et al. (1996), the strongest relationship between Type A and coronary heart disease was found in studies published before 1978. Furthermore, Myrtek's (2001) meta-analysis found no reliable relationship between Type A and coronary heart disease, and although the meta-analysis showed a weak relationship between hostility and coronary heart disease, the author concluded that the effect was so small as to be of negligible practical significance.

These more recent meta-analyses are noteworthy for pointing out that a number of studies sampling low-risk individuals showed no relationship at all between the Type A Behavior Pattern and coronary heart or a negative relationship between the two variables. Miller et al. (1996) found one factor responsible for the lack of consistent findings was a problem of range restriction. Many studies selecting participants for inclusion underrepresented initially healthy individuals. Age may also explain some of the inconsistencies, with stronger effect sizes found in younger samples than older samples. Furthermore, more recent research suggests no significant relationship exists between the Type A Behavior Pattern and cardiovascular and non-cardiovascular mortality (e.g. Šmigelskas et al., 2015). A recent examination of internal documents suggests that much of the research showing a strong apparent relationship between the Type A Behavior Pattern and coronary heart disease was funded by Philip Morris, a tobacco corporation (Petticrew, Lee, & McKee, 2012), hence suggesting the possible presence of a conflict of interest. One consequence of the inability to replicate the initial findings purporting to establish a relationship between Type A/B Behavior Pattern and cardiovascular heart disease or mortality is the increased skepticism about the legitimacy of the Type A/B Behavior Pattern as a concept. Petticrew et al. (2012) contend that contemporary research in which the Type A/B trait is used as a predictor variable amounts to "zombie science." In the process, with regard to physical health outcomes, researchers have largely abandoned the construct, with the possible exception of those providing evidence of further debunking the link between Type A/B Behavior Pattern and measures of physical health (e.g. Šmigelskas et al., 2015).

Type A/B Behavior Pattern and Aggression

The Type A/B Behavior Pattern has also been studied as a potential predictor of several behavioral outcomes. One initially promising line of research examined the potential of the Type A Behavior Pattern to moderate the relationship between provocation and aggression in adults. In a meta-analysis conducted by Bettencourt, Talley, Benjamin, & Valentine (2006), the Type A Behavior Pattern was classified as one of a set of personality traits under the category of susceptibility to provocation. As noted by Bettencourt et al. (2006), early experiments demonstrated that when provoked or frustrated, Type A individuals typically experienced greater feelings of anger or irritation and greater desire to harm those whom they believed provoked or frustrated them than Type B individuals.

Several early experiments showed a tendency for Type A individuals to behave more aggressively than Type B individuals under highly provoking or frustrating conditions, but not under neutral or nonprovoking conditions. A meta-analysis by Bettencourt et al. (2006) essentially confirmed that the above pattern of findings was relatively reliable, although inconsistent, especially among later experiments. In addition, the most recent two experiments included in the meta-analysis failed to show a positive relationship between the Type A Behavior Pattern and aggression under either provoking or nonprovoking conditions (e.g. Edguer & Janisse, 1994), thus repeating a pattern found in research examining a relationship between the Type A Behavior Pattern and various measures of physical health.

Personality and Cancer

Alv A. Dahl

Oslo University Hospital, The Norwegian Radium Hospital

How Can Personality Be of Importance in Cancer?

Personality can affect cancer-related processes in several ways: (1) through long-term affection of the brain ("the organ of personality") influencing its central coordinating influence on neuronal, neuroendocrine, and other major regularly processes; (2) through unhealthy life style as a consequence of abnormal personality traits; (3) through long-term negative affective states associated with anxiety disorders, depression, or substance use disorders or less adaptive coping mechanism; (4) by being a causal factor for somatic diseases (like ulcerous colitis) or mental disorders (like posttraumatic stress disorder) that predispose cancer development.

In order to explain the interaction between the personality and biological systems, several models have been developed. Here I present three of the simplest, and I use immunological changes as the mediator between personality and cancer.

The stability model focuses on the permanence of the personality as a causal factor. Although the immune system can respond rapidly, it is the long-term changes that are relevant for cancer development. A problem with this model concerns the stability of immunological measurements over time.

The interaction model emphasizes the interaction between the personality and more situational variables and focuses on critical periods of the cancer trajectory. An example is successful surgical extirpation of the malignancy, and the immunological and emotional changes that follow such an important biological event. Negative life events affect persons differently due to their coping strategies. For example, a high level of optimism has been associated with a high level of immunological substances while the person is under stress, and thereby optimism buffers the negative immunological effects of the disease.

Personality affects how a person interprets and reacts to stressors, and thereby the psychic influence on biological systems is amplified or reduced. Persons thereby have their characteristic and permanent profile concerning cardiovascular, neuro-endocrine, and

cellular-immunological reactivity in relation to stressors. Over the years, variations in reactivity profiles can be of relevance for cancer development.

The integrated model states that permanent stressors, chronic depression, lack of social support, and other negative psychosocial factors can influence transition into and development of cancer. However, they did not consider high neuroticism as a common mediator in relation to many of these factors. These factors interact with hormonal stress response, circadian rhythms, erogenous viruses, and immune responses contributing to the development of cancer.

Personality and Risk of Cancer

An eventual direct link between various personality traits and increased risk of cancer development has been investigated in many studies. Here I will just present findings from a representative study in order to present the methodology applied. A study based on six population-based samples of altogether 42,843 persons among whom 2,156 developed cancer during a mean of 5.4 year follow-up, found no significant associations between the Big Five personality traits and cancer development (Jokela, Batty, Hintsa, Elovaino, Hakulinen, & Kivimäki, 2014).

As there is a considerable association between personality and depression, I briefly present a meta-analysis of the association between depression and cancer. No significant associations between depression and cancer, but increased level of depressive symptoms increased the risk of cancer-specific mortality by 25% and the depression-specific mortality with 39% (Satin, Linden, & Phillips, 2009). Although there are a few deviations, there is solid evidence for the conclusion that there is no direct significant association between personality traits and increased risk of development of cancer.

Personality and Screening and Counseling Concerning Cancer

Among women under 50 with a high level of education and regular mammography was significantly associated with basic traits like high conscientiousness and high extraversion, as well as lower level of depressive symptom. Personality traits associated with irregular mammography could be associated with the opposite personality profile, but this has been less researched similarly to official campaigns for cervical smears. Genetic counseling seeks to inform the individual as precisely as possible his/her risk of cancer due to the presence of hereditable mutations. Several studies have shown that individuals with low level of optimism (high level of pessimism) reported such counseling as stressful. The same was observed in women with high levels of neuroticism.

To sum up, both cross-sectional and longitudinal studies have demonstrated that personality factors significantly influence acceptance of and distress related to cancer screening and genetic counseling. Organizers of such health care programs should consider this in their planning.

Personality and the Diagnosis of Cancer

There are relatively few studies on the influence of personality on coping with a cancer diagnosis. Individuals with high levels of optimism and low levels of neuroticism are less disposed to mental distress reactions both at diagnosis and 12 months later. All studies lack personality measurements before diagnosis, and even if we presume stability of basic personality traits, they can change as a consequence of the trauma of a cancer diagnosis.

Personality and Cancer-specific Mortality

A meta-analysis of 157 studies of the associations between psychosocial stress and cancer survival concluded that cancer patients who reacted with marked distress or maladaptive coping mechanisms had 11% poorer survival and 125% increase in mortality. All the personality factors studied had strong associations with high neuroticism (Chida et al., 2007).

Several prospective studies with sufficient statistical power have all reached the same conclusion: high neuroticism is significantly associated with raised general mortality, but not with cancer-specific mortality. This is what the study by Jokela et al. (2014) concluded.

Personality and Cancer Survivorship

There are several definitions of cancer survivorship, such as intermediate (1 to 5 years since diagnosis) and long-term (more than 5 years since diagnosis). Several studies of optimism in breast cancer survivors have reported both significant and nonsignificant associations in intermediate survivors.

Few studies have yet examined personality in relation to long-term survivorship. In testicular cancer survivors at a mean of 11.4 years after diagnosis, high neuroticism was significantly associated with chronic fatigue, relapse anxiety, mental distress, neurotoxic side effects after chemotherapy, increased levels of somatic symptoms, and increased use of alcohol and anxiolytics (Grov, Fosså, Bremnes, Dahl, Klepp, Wist, et al., 2009).

Can Cancer Change the Personality?

To become a cancer patient obviously changes the narrative part of the personality, and the new identity as a cancer patient could make more or less impact on coping styles and values in life. Posttraumatic growth refers to positive personality changes owing to the struggle with the trauma of cancer, and not due to the trauma itself. The concept is currently understood in two ways, either genuine personality changes or psychological defence (reaction formation) against the painful physical and emotional consequences of cancer. The relationship of basic personality traits to posttraumatic growth is far from settled.

Personality, Lifestyle, and Cancer Prevention

Unhealthy lifestyle characteristics such as smoking, being overweight, hardly any physical activity, unhealthy diet, hazardous use of alcohol, increase the risk of cancer development, cancer recurrence, cancer-related mortality, and severe co-morbid conditions like cardio-vascular diseases or diabetes. Lifestyle is strongly associated with various personality traits.

High intake of fruits and vegetables protects against the development over several cancer types. A review states that such intake is significantly associated with an effective self, control over behavior and motivational control, and such behavior is definitely associated with high conscientiousness (Shaikh et al. 2008).

A meta-analysis of 33 studies showed that high neuroticism was significantly associated with less *physical activity*, while high extraversion and conscientiousness were associated with more activity (Rhodes & Smith, 2006).

An analysis of nearly 80,000 persons showed that high extraversion and neuroticism, and low conscientiousness were significantly associated with daily *smoking* (Hakulinen, Hintsanen, Munafò, Virtainen, Kitvimäki, Batty, & al., 2015). In the same material, high extraversion and low conscientiousness were significantly associated with *high alcohol consumption,* and transition from moderate to high alcohol consumption over time.

A meta-analysis of 194 studies of *conscientiousness* showed that a high score on this personality trait was significantly associated with less smoking, alcohol consumption, violence, risky sexual behavior, or suicidality. In a lifetime perspective, high conscientiousness was significantly associated with a healthy lifestyle and longer lives (Martin, Friedman, & Schwartz, 2007).

The Future of Personality and Cancer

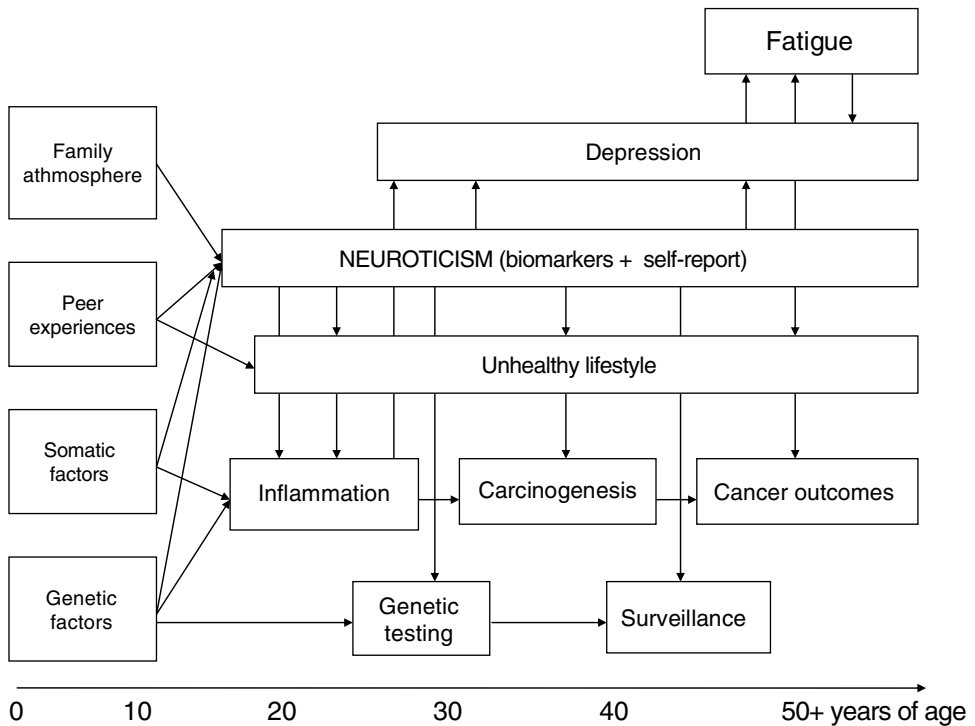
High neuroticism is the main personality trait related to various aspects of cancer, its trajectories, and adverse effects (Lahey, 2009). Neuroticism is strongly related to depression and fatigue that also have been in focus concerning cancer development and prognosis. Unhealthy life style is also associated with deviant personality traits, and an inflammatory-network model for cancer development has been based on such factors and other types of environmental factors. Personality patterns are established early in life, and they influence the "interior milieu" over decades. Researchers have therefore emphasized that a lifetime perspective is mandatory for identification of etiological factors related to life style diseases including cancer. Ben-Shlomo & Kuh (2002) defined this perspective as follows: "the study on long-term effects on chronic disease risk of physical and social exposures during gestation, childhood, adolescence, young adulthood and later adult life. It includes studies of the biological, behavioral and psychosocial pathways that operate across an individual's life course, as well as across generations, to influence the development of chronic diseases." The lifetime approach demands an understanding of the natural development of biological and psychological systems over time. In his 2008 paper: "The multiple linkages of personality and disease" Friedman described several models for the association between personality and diseases, and he concluded: "A frustrating fact of life is that it is often true that more than one linkage is simultaneously causing an observed association, but most study designs cannot detect multiple causal linkages. In other words, many health outcomes are multidimensional and are multiply and complexly determined; the phenomena thus push us to the limits of model construction and research design and analysis."


Figure 1 Lifetime model of the relationship between neuroticism and cancer.

Along these lines, I present a more complex model for the association between personality traits and cancer development for future studies (Figure 1). [Figure 1 near here]

Resiliency and Hardiness

Salvatore R. Maddi

University of California, Irvine

Introduction

Some psychologists consider resilience to emphasize how people can remain the same despite the imposition on them of stressful circumstances. One emphasis of this position is that it is helpful to avoid stresses. In contrast, personality hardiness emphasizes resilience as the process of change, growth, and development that is provoked by dealing with, rather than avoiding stressful circumstances (e.g. Maddi, 2002; Maddi & Khoshaba, 2005).

In this regard, an assumption behind personality hardiness is that life is by its nature changing and stressful, so involving oneself in this process helps one grow and develop toward greater fulfillment. This assumption derives from the existential position (Kierkegaard, 1954) that everything we do in life is the result of making decisions. As life is on ongoing process of change, each decision with which we are faced involves choosing the future or the past. Although choosing the future is developmentally best, it brings anxiety because the outcome cannot be predicted in advance. But, if we decide to avoid anxiety by choosing the past (i.e. what we already know and are doing), we encounter the existential guilt of missed opportunity, boredom, and emptiness of living.

Based on this, the hardiness approach assumes that, in one's ongoing living, the best way to establish a pattern of choosing the future, rather than the past, is to develop the personality pattern of hardiness. In this, hardiness is considered a pattern of attitudes and strategies that help one do the hard work of choosing the future rather than the past (Maddi, 2002). The more than 40 years of research, consulting, and counseling that emerged from this conceptualization has solidified the position. Early on, Maddi's work involved showing that people who express more interest in change are also likely to be more creative in their work. But, in specifying the personality characteristics involved more completely, and the particular effects of stresses on functioning, it seemed important to carry out a relevant experiment, rather than just doing correlational research.

The Illinois Bell Telephone Project

In the 1970s, Maddi was a consultant for Illinois Bell Telephone (IBT). At that time, the US telephone industry was a federally regulated monopoly, whose member companies only had to provide a cheap and reliable telephone service, and did not have to worry about their bottom lines. But, it became clear that this situation had to change, as the beginning of the internet was opening up the field, and encouraging international competition. The US government made clear that the telephone industry would need to be deregulated in order to motivate competition for greater possibilities and income in the newly developing circumstances.

With the help of IBT decision-makers, Maddi and his research team in 1974 began yearly testing of 450 managers, in a longitudinal research study to determine the effects of the deregulation on them. Each yearly testing included questionnaires and interviews. Also available were yearly job performance evaluations done by the company. Six years into the study (in 1980), the federal deregulation occurred, as a major disruption on the industry and its companies. In the year following the deregulation, nearly half of the managers in our sample were terminated. In the research, we continued to test the managers, whether they continued or were terminated, with the questionnaires, interviews, and job evaluations each year for the following six years. The study is still regarded as a classical natural experiment.

The study results showed that, in the deregulation years, nearly two-thirds of the sample fell apart in various ways. There were clear signs of major anxiety, depression, and anger, undermining performance at work. These signs included violence, data loss, inability to make decisions, and decision-making avoidance. And, in home life, there were also signs of being undermined, such as divorces, substance abuse, and even suicides.

In contrast, the other third of the sample not only survived, but also thrived, following the deregulation. At work, they either rose up in the ranks, or if they were among those terminated, they found significant jobs in other organizations, or even started their own companies. In all this, they were able to give and get social support with their significant others (at work, or at home) and were able to grow and develop by dealing effectively with the deregulation stresses.

Of particular importance in developing Hardiness assessment was the comparison of managers who reacted resiliently to the deregulation stresses with those who did not (Maddi, 2002). The managers who reacted well to the deregulation had, in the six years before this upheaval, been much stronger than the others in the attitudes of commitment, control, and challenge. No matter how bad things might get, they wanted to stay involved with people and contexts (commitment), continue to struggle to have an influence on outcome (control), and learn how to grow and develop by trying to deal effectively with stresses (challenge). In contrast, the managers who fell apart under the deregulation had even before it showed definite signs of playing it safe by avoiding stresses, and if unsuccessful in this, by sinking into alienation and powerlessness. These results led to conceptualizing hardiness as the attitudes (the 3Cs of commitment, control, and challenge) and strategies (problem-solving, rather than avoidance, coping; socially supportive, rather conflictful, social interactions; and beneficial, rather than overindulgent, self-care). It appeared that the hardy attitudes provided the courage and motivation to be able to do the hard work of hardy strategies that turned stresses into growth advantages. All this is quite

consistent with the existential view, well summarized by Nietzsche as "whatever doesn't kill me makes me stronger."

Specifically, the pre- and post-deregulation data permitted a study (Khoshaba & Maddi, 1999) of the early-life experiences of managers on performance after the deregulation. This showed that the managers who thrived on the deregulation had reported remembering a more disruptive, stressful early family life, and having been selected by their parents as the hope of the family. They indicated having accepted this role and working hard to justify it. These results are consistent with the assumption that hardiness can be learned, rather than being inborn. It also indicates that parents can help their children grow in hardiness by having them know that life is by its nature stressful, and that involving themselves in this, rather than denying it, is the way to grow and develop toward a better life. In contrast, parents who are overprotective and controlling may be jeopardizing their children's growth toward hardiness.

Further Evolvement of the Hardiness Approach

In the years since the IBT study, there have been many additional research studies and consulting work on the hardiness approach. In this process, our various versions of the hardiness questionnaire have been translated into more than 15 Asian and European languages, and are also used in English in numerous countries. There have also been reviews of hardiness research (e.g. Maddi, 2002). In the research studies covered in these reviews, it has been shown that the hardy attitudes are positively related to each other, and to the hardy strategies of problem-solving coping, socially supportive interactions, and beneficial self-care. This hardiness pattern has been positively associated with enhanced performance, conduct, mood, and health in samples of college and high-school students, and working adults in military, firefighting, sports, and business contexts (e.g. Maddi, 2002).

In the process of research and consulting, there has been systematic improvement of hardy attitudes measurement. Over the years, the measure has been shortened and improved. The current version (Maddi, 2001) is the 18 Likert-item Personal Views Survey, III-R (3rd edition, revised). Examples of items are, for commitment, "I often wake up eager to take on life wherever it left off"; for control, "When I make plans, I'm certain I can make them work"; and for challenge, "Changes in routine provoke me to learn." Chronbach Alpha coefficients for all three Cs range in the .70s, and for total hardiness are even higher. The 3Cs are positively correlated, and each of them shows a high correlation with the total hardiness score. Also, consistent with hardiness theorizing, Sinclair & Tetrick (2000) have found that factor analysis of the hardiness test items yields the three empirically related first-order factors of commitment, control, and challenge, and that these factors are indeed positively related to the second-order factor of hardiness. This pattern has supported the conceptually-emphasized use of a total hardiness score. In another study (Maddi & Harvey, 2005), no cross-cultural or demographic differences were found in hardiness.

By now, there are many especially significant studies on the role of hardiness in various performance, conduct, and health activities (Maddi, 2002). For example, in samples of bus drivers, lawyers, and nurses, hardiness was found to be positively correlated with measures of performance and satisfaction, and negatively correlated with anxiety and depression.

There are also similar findings in American employees experiencing the culture shock of work missions abroad, and foreign immigrants to the United States. In a study of sports performance, hardiness levels of male, high-school varsity basketball players were measured in the summer, and then their performance was obtained in the ensuing season. Hardiness predicted six out of seven indices of performance in the expected direction, even though all the subjects were varsity players.

Also, there have been studies (Maddi,2002) concerning hardiness and military personnel. For example, it was found that soldiers high in hardiness adjusted better to health and life stresses than did those who were low in hardiness. Further, among soldiers returning from operational deployments, there was a positive relationship between hardiness and readjustment to former lives. Also found was a positive relationship between hardiness and leadership behavior among US Navy cadets. Hardiness was also a positive predictor of performance success in soldiers undergoing special forces training among Norwegian Naval Academy cadets. Similarly, there was a positive correlation between hardiness and both retention and performance excellence in US Military Academy cadets. In addition, there are studies showing that hardiness is negatively related to conduct problems, such as alcoholism, drug use, and gambling (Maddi, 2002).

Comparison of Hardiness and Other Possible Predictors

Understandably, questions have arisen as to whether hardiness is little more than some other personality variable. This has led to several empirical studies comparing hardiness and other possible predictors of performance, such as negative affectivity, neuroticism, optimism, and grit. These studies support the conceptualization of hardiness as separate from these other variables (Maddi, 2002).

Hardiness Practical Applications

There is a growing need for hardiness assessment and training, due to the increased rate of social, technological, and cultural change being fueled by our transition from industrial to information societies. Trying to adapt to the pressures of change, companies are continually restructuring (e.g. decentralizing, merging, downsizing, upsizing), which certainly influences the lives of employees. In the attempt to help individuals deal well and grow with all these changes, Maddi and Khoshaba have developed hardiness assessment and training procedures that can be used in consulting with individuals and organizations.

As to hardiness assessment, there is now the HardiSurvey III-R, a valid and reliable 65 item-questionnaire that measures the vulnerability factors of stress, strain, and regressive coping, along with the resilience factors of hardiness attitudes, problem-solving coping, and supportive social interactions (Maddi & Khoshaba, 2001). The vulnerability and resilience factors of the test-taker are compared with each other, and with available norms, leading to a wellness ratio. This test can be taken on the website (www.HardinessInstitute. com), and leads to you receiving a comprehensive report concerning your resilience

or vulnerability under stress. As to hardiness training, there is now a comprehensive workbook (Khoshaba & Maddi, 2008) that includes instructions, exercises, case studies, and evaluation procedures concerning how to engage in problem-solving (rather than avoidance) coping, socially supportive (rather than conflictful) interactions, and beneficial (rather than overindulgent) self-care. Also shown is how to use what is learned through these procedures to deepen your hardy attitudes of commitment, control, and challenge, so that once the training is over, you will have the courage and strategies to do the hard work involved in improving your functioning in everyday living.

There are some studies showing the effectiveness of the hardiness training procedure in high-risk managers, and undergraduates (Maddi, 2002). In these studies, as expected, training improved performance, emotional states, and hardiness.

Concluding Remarks

In terms of conceptualization and empirical support, it appears that the hardiness approach has growing validity. This encourages its use in assessment and training, to increase the likelihood that individuals and organizations will be able to turn stressful circumstances from potential disasters into growth opportunities instead.

Personality and Risk-Seeking

Joseph Glicksohn and Revital Naor-Ziv

Bar-Ilan University

Some readers have enjoyed bungee jumping, and others would like to try this; a third group of readers, in contrast, cannot even contemplate the thought of jumping off a cliff and "hoping for the best." The riskiness of an activity is a subjective appraisal. Thus, risk-seeking and personality should be considered in tandem. Risk comes in two guises. One is its meaning in the economic or decision-making literature referring to the variability of the options available to the decision maker. For example, choosing between receiving $50 now, or entering a lottery, with two options: the possibility of receiving $100 with a probability of 0.5, or of receiving $0 with the same probability. The first case is a sure bet (no loss, and no uncertainty – hence no risk); the second bet has a certain amount of risk associated with it – even though the expected amount to be won remains the same ($50). A risk-seeker might well opt for the second bet. There might even be a particular personality profile associated with such behavior, though this usually boils down to the distinction between a risk-seeking and a risk-averse personality in that decision-making situation. Thus, one might be risk-seeking when contemplating a future loss, and risk-averse when considering a future gain. Such instrumental risk-taking involves considering future outcomes, both the positive but especially the negative. Some individuals are more careful in their decision-making here, and trait anxiety is one such individual difference related to being concerned with such possible negative outcomes.

The second meaning attributed to risk-seeking is that of engaging in risky behavior, such as gambling or the use of recreational drugs, having a possible negative consequence (either immediately or in the long-term) for the risk-seeker and/or for others. For example, engaging in a risky sport such as skydiving or mountaineering, wherein accidents do happen, is an attractive option for risk-seekers, and an absurd one for those who are not risk seekers. Such recreational risk-seeking, implicates two personality traits: impulsivity and sensation seeking (or venturesomeness). The difference between these two traits is itself indicative of the form of risk-taking that might be engaged in. Sybil Eysenck (1993, p. 144) distinguishes between the two traits by means of an "analogy to a driver who steers his car around a blind bend on the wrong side of the road. A driver who scores high on Imp[ulsivity]

never considers the danger he might be exposing himself to and is genuinely surprised when an accident occurs. The driver who scores high on Vent[uresomeness], on the other hand, considers the position carefully and decides consciously to take the risk." Impulsivity implicates impulsive decision-making, hence possibly incurring risk, but not necessarily involving risk-seeking *per se*. Sensation-seeking refers to the active seeking of novel experiences, some of which involve risk, hence implicating risk-seeking. Whether impulsivity and/or sensation-seeking is involved in risk-seeking in the economic sense will be dependent on whether the impulsive individual never considers the possibility of actually losing the bet (winning nothing), and whether the sensation seeker decides consciously to take the risk of winning a larger sum of money. The anxious individual is concerned with the possible negative outcomes of risky behavior; the sensation-seeking individual tends to depreciate the riskiness of the situation. One should note that those involved in recreational risk-seeking do not necessarily exhibit risk-seeking behavior in the financial domain.

Risk-seeking can implicate antisocial behavior, especially if the activities engaged in are prohibited by law, such as gambling and the use of recreational drugs. Dangerous driving is a common problem to society, the individual endangering both self and others. Risk-seeking, however, can also implicate prosocial behavior, especially if the risky activities engaged in can save lives. Among these individuals, one would count members of the police, the fire department, rescue teams, and so forth. Such individuals score high on measures of sensation-seeking, in particular the scale indicating "thrill and adventure seeking." Individuals scoring high on this scale are also found amongst those engaged in risky leisurely activities such as rock climbing. Of course, business and pleasure can be mixed if the prosocial sensation seeker is a member of a rescue team. Others are risk-seeking in their leisure time, engaging in risky sports. Risk-seeking is not, however, an all-encompassing lifestyle: Risk seekers choose the risks they want to engage in. Those engaged in such risky activities tend to downplay the amount of risk involved, viewing their proficiency as being more indicative of their skills than of a risk-seeking inclination. In this respect, they are nonimpulsive sensation seekers: for them, they take "calculated risks," which are dependent on their level of proficiency in the activity. Indeed, one cannot engage in a risky profession or a risky sport and be cavalier about this. Planning, the use of the right equipment, training, physical ability, and experience are all part and parcel of the endeavor. Those engaged in risky sport can match their ability to the demands of the situation, experiencing flow. Such individuals score high on a second scale of sensation-seeking indicating "experience seeking." A whole tourist industry is built on such a combination of risky sport, risk-seeking, and the experience of flow. With increasing experience, risk-seeking is exchanged for more skillful performance. Those who are not high sensation-seeking risk seekers will not engage in the types of high-risk sport (surfing, skydiving, and so forth) that require such skills. Other personality traits that are involved here are self-efficacy and ego stability (i.e. low neuroticism).

There is also a dark side to risk-seeking. Some individuals engage in activities that are detrimental to society (antisocial risk-taking). Among such activities one would count various forms of reckless behavior (e.g. driving while under the influence of drugs or alcohol, bulimia), criminal behavior, and impulsive behavior. Such individuals score high on impulsive sensation-seeking, indicated in the scale assessing "disinhibition"; they also score high on trait impulsivity. Risk-seeking here is the risk involved in such activities. This might

involve long-term risk, such as an unwanted pregnancy, health complications associated with unprotected sexual activity, eating disorders, risks involved in the use of tobacco, alcohol, and other drugs, etc. Given that it is primarily impulsivity that is implicated here, it is not necessarily the case that these individuals are risk-seeking; indeed, they might not even be aware of the risks involved. The thought that one can move people over from the dark side, while still preserving their risk-seeking inclination, is a viable option. Thus, instead of using drugs, one could engage in risky sport; instead of being a computer hacker, one could find employment as a security analyst. Risk-seeking would thus be channeled into a social or perhaps prosocial activity. This, however, is an option that might work with high sensation seekers, but not with high impulsive individuals, because one's decision-making should not be impulsive, if one considers taking the risk-seeking option.

With increasing exposure to and experience of risk, perceived risk tends to decrease – especially for high sensation seekers. For those engaged in risky sports, this is usually accompanied by a self-perceived increase in mastery, competence, or proficiency in that activity. Just as sensation seeking is a trait wherein one strives for new and novel experiences – the high sensation-seeker is on a continual upward path of calibration and recalibration of the range of experiences that have been assimilated – so the risk-seeking of the high sensation seeker must balance between present skill and proficiency and the challenge of the quest. The resulting flow experienced by the mountain climber will only result when this balance is sustained. One's experience is, in part, one's interpretation of that experience, based on this balance between risk and competence. Given that trait considerations (e.g. sensation-seeking) are only part of the state-trait interaction that determines experience, risk-seeking must also be partly determined by changes in state. It is here that impulsivity, which is not only a trait but is also a state-dependent phenomenon, can play a critical role. For example, alcohol can result in impulsive decision-making; and cigarette smoking can be relaxing, but can also serve to keep one's impulsivity in check. Risk-seeking is thus both a function of one's degree of sensation-seeking – whether this be through high-risk, physical activities as implicated by one's "thrill and adventure seeking" predisposition, or through the mind, as implicated by one's "experience-seeking" predisposition, or both – and one's state of consciousness. It is important to stress that sensation-seeking is not risk-seeking *per se*. True, risk is involved, but as Marvin Zuckerman has stressed "although sensation seeking is defined by a tolerance for risk, risk is not the point of it" (Zuckerman, 2007, p. 58).

This, however, might not necessarily be the case among adolescents, who are characterized as being higher than adults in sensation-seeking, impulsivity, and risk-seeking. The study of personality and risk-seeking in adolescence has become a major area of research in recent years. Sensation-seeking is found to follow a curvilinear trend, increasing in early adolescence (ages 10–15), peaking during late adolescence (ages 16–19), and declining thereafter; and this was once proposed to be a finding having no clear developmental explanation. In recent years, a neurodevelopmental explanation has been proposed, namely the similar curvilinear trend for the maturation of subcortical structures, which are related to affective processing leading to the search for novel experiences – hence, driving sensation-seeking. Impulsivity, in contrast, is found to follow a linear trend, decreasing progressively during adolescence. The proposed neurodevelopmental explanation for this is the corresponding monotonic maturation of the prefrontal cortex and its executive functions such as planning and decision-making, which are impaired in impulsivity. Not only do these

differential developmental trends provide an influential neurobiological framework for both impulsivity and sensation-seeking, they also suggest that these two traits are different, though related. This proposition has been referred to as the "dual systems model." Risk-seeking is thus viewed as resulting from this critical combination of heightened sensation seeking with limited capacity for executive functioning (impulsivity). Adolescence is also characterized by the influence of peers on the adolescent's behavior. Thus, risk-seeking can be dependent on peer influence. Furthermore, high sensation seekers trend to prefer the company of other high sensation seekers, which naturally leads to common sensation-seeking and risk-seeking pursuits. This can result in experimenting with drugs, or participating in risky sports. The adolescence-limited onset of delinquency is also dependent on this critical juxtaposition of neurobiological, cognitive, and social factors during adolescence.

Two influential tasks have been developed to reveal risk-seeking in the lab. In the Balloon Analogue Risk Task one pumps up balloons to win money. If a balloon bursts, the money is lost. The more one pumps, the riskier it gets. In the Iowa Gambling Task, one chooses a card from one of four stacks, resulting in either a gain or loss of money. Some stacks are high risk, involving high pay-off, sometimes, but also high penalty, sometimes. These tasks have been investigated in relation to both sensation seeking and impulsivity, in both adults and adolescents. In turn, performance on these tasks has been related to substance abuse, gambling, eating disorders, and other risky behaviors. One notes greater risk-seeking in late adolescence and emerging adulthood, relative to both younger and older ages.

It is important to stress that risk-seeking is not necessarily a negative thing, as implicated in health risks or antisocial behavior; risk-seeking can be channeled into prosocial activities, such as volunteering or working in high-risk prosocial professions, but also into skillful engagement in risky sports. Risk-seeking can also surface as "thinking outside the box." The traits of impulsivity and sensation-seeking are inherently related to risk-seeking. The study of risk-seeking without a consideration of personality would be a risky venture.

Personality and Suicide

Melanie L. Bozzay and Edelyn Verona

University of South Florida

Suicide is a significant public health problem worldwide, resulting in the deaths of more than 800,000 people every year (World Health Organization, 2014). Since these deaths are behaviorally driven, and thus, to some extent, preventable, research in this area emphasizes identifying factors that may increase risk of suicidal behavior. Environmental factors, such as adverse life experiences and stress, are particularly emphasized, since mental disorders (e.g. depression) and self-destructive behaviors (e.g. nonsuicidal self-injury) linked to suicide may be reactions to these experiences. Other factors contributing to suicide are specific to the individual, often stemming from genetic or biological factors, albeit shaped by experience, that increase the likelihood of suicidal thoughts and behaviors. Personality traits are of particular relevance to suicide research since they may aid in ascertaining which individuals are more predisposed to consider or engage in suicidal behavior in response to difficult circumstances.

Personality traits are relatively stable patterns of behavior, cognition, emotion, and motivation that an individual displays across different situations. Personality is theorized to develop from temperamental dispositions, essentially biobehavioral tendencies related to emotional states (e.g. activity level, fear reactivity) that initially emerge in infancy (Thomas & Chess, 1977). These temperamental dispositions are biologically determined to some degree, as they are partly heritable, and linked with physiological processes. However, the environment is thought to have an important role in shaping which dispositions later become stable personality traits, by encouraging the expression of tendencies that may be most useful for each individual in certain situations over time.

Since personality traits partially determine behavior, they may be relevant in identifying which individuals are more likely to exhibit psychopathology. One conceptualization posits that personality traits predispose individuals to develop psychopathology. Alternatively, psychopathology (e.g. anxiety) may be the manifestation of extreme expressions of personality traits (e.g. Stress Reaction). Regardless, there is literature to indicate that personality traits and psychopathology stem from common biopsychological processes (e.g. deficient inhibitory control), suggesting they are interrelated to some degree. Indeed, personality

traits have been linked with broader dimensions of psychopathology implicated in mental disorders. Research indicates that mental disorders are interrelated to some degree and cluster around at least two main dimensions of internalizing and externalizing psychopathology. Specifically, research by Krueger has shown that symptoms of psychopathology and personality traits (e.g. disconstraint, negative emotionality) are both linked to these dimensions (Krueger and Piasecki, 2002). Specifically, the internalizing dimension is typified by symptoms and traits that include a tendency to react negatively to situations that induce strong emotions, and to experience internal distress. This internalizing tendency is considered a core feature that is expressed, albeit differently, in psychopathology including depressive and anxiety disorders. In contrast, the externalizing dimension encompasses personality traits associated with antisocial behavior, as well as impulsive and sensation-seeking tendencies, behaviors that underlie psychopathology such as substance use and antisocial personality disorder.

Importantly, the internalizing and externalizing dimensions that have emerged in psychopathology research may be paralleled in two broad subtypes of suicidal individuals identified by Apter et al. (1995). The *depressed or withdrawn subtype* encompasses individuals who exhibit emotional and behavioral characteristics of internalizing symptoms, including depressed mood, self-blame, somatic disturbances (e.g. loss of appetite, sleep difficulties), and an increased negative response to difficult circumstances. In contrast, the *irritable or aggressive subtype* is comprised of individuals who display externalizing symptoms, such as anger, frustration, impulsivity, and reduced self-control (particularly with regards to substance use, as well as aggressive and nonsuicidal self-injurious behaviors). Notably, these subtypes appear to correspond to different aspects of suicide risk. That is, individuals who are primarily depressed or withdrawn show more chronic suicidal thoughts and engage in planning a suicide attempt. While depressed or withdrawn individuals who consider suicide are naturally at increased risk of engaging in suicidal behavior, they tend to engage in attempts that are lower in lethality, perhaps due to energy deficits associated with depression. In contrast, individuals who are primarily irritable or aggressive may consider suicide, but these thoughts may be tied to rapid mood swings in reaction to temporary emotional situations (e.g. conflict, incarceration) rather than chronic depressed mood. However, they seem to be more likely to engage in suicide attempts, often more severe in nature, perhaps due to impulsiveness and higher immunity to violence.

Models of personality may aid in describing the characteristics of individuals who comprise the depressed/withdrawn and irritable/aggressive suicidal subtypes. One of the best-known models, the Five Factor Model, describes personality traits as being encompassed by five general characteristics. These characteristics are openness to experience, conscientiousness, extraversion, agreeableness, and neuroticism/emotional stability (McCrae & Costa, 1989). However, other personality models exist that have a stronger basis in the temperament and emotion literature, in particular as exemplified by Tellegen's three factors (e.g. Tellegen & Waller, 2008). In Tellegen's model, Negative and Positive Emotionality describe the propensity to experience negative and positive affect, respectively, across situations, while Constraint describes tendencies to control or inhibit behavior. Notably, research demonstrates that dimensions in the Tellegen and Big Five models are largely interchangeable (see Table 1; Church, 1994).

Table 1 *Relationships between Tellegen's Three Dimensions and the Five Factor Model* Characteristics

Five Factor Model	Tellegen's Model
Neuroticism, agreeableness	Negative Emotionality
Extraversion, conscientiousness (stability)	Positive Emotionality
Openness to experience, conscientiousness (impulse control)	Constraint

Since Tellegen's model has been previously employed in linking personality to emotional states related to suicide and externalizing psychopathology (Verona & Patrick, 2000), and research has tied these dimensions to genetic and biopsychological processes, it may provide a useful framework in summarizing the literature linking personality traits, psychopathology, and suicide risk. Indeed, research indicates that each of Tellegen's dimensions has unique relationships with broad dimensions of psychopathology, as well as specific mental disorders, connections that contribute differently to varying aspects of suicide risk. We outline these relationships more fully below.

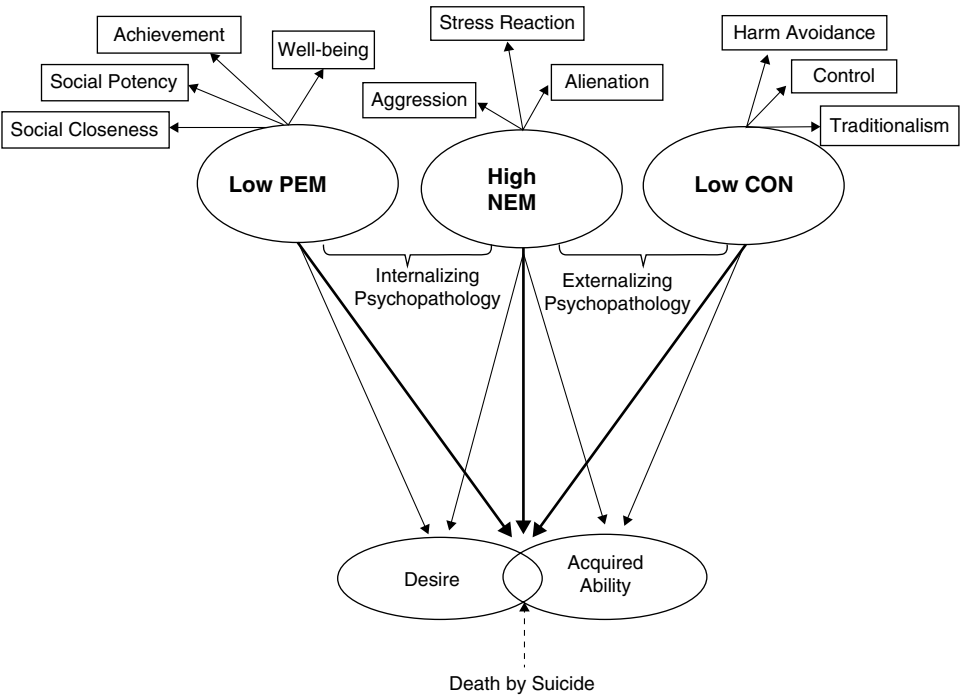
Low Positive Emotionality (PEM) has been linked with internalizing psychopathology implicated in suicide risk, as well as suicidality more generally (see Figure 1) . PEM typifies the tendency to experience positive emotions across situations, and is comprised of achievement, social closeness, social potency, and well-being traits. Individuals with low PEM have difficulty maintaining a positive disposition, feeling in control in life, feeling close


Figure 1 Model describing the interrelationships of personality factors, dimensions of psychopathology, and aspects of suicide risk.

with others, and asserting needs. Since these tendencies have implications for the individual's social functioning and perceptions of situations, aspects often utilized for developing and implementing coping strategies in times of stress, individuals with lower PEM may have fewer options to manage distressing circumstances. Perhaps consequently, lower levels of this dimension represent risk for developing internalizing psychopathology characterized by deficits in the ability to experience positive affect. Indeed, depression is most associated with increased suicide risk. And, since PEM is also implicated in feelings of competence, it is unsurprising that individuals low on this dimension are more likely to experience feelings of hopelessness that the future will improve or change, and hence, potentially more likely to consider suicide. There is also evidence to suggest that individuals low on this dimension are more likely to engage in self-directed harm such as suicide attempts (Yen et al., 2009).

Negative Emotionality (NEM) has also been linked with varying aspects of suicide risk. It is comprised of aggression, alienation, and stress reaction personality traits. These traits promote tendencies toward distress, irritability, and anxiety across situations, as well as estrangement and distrust of others in social relationships. NEM represents a general risk factor for various forms of psychopathology, including internalizing (e.g. depressive and anxiety-related disorders) and externalizing (e.g. aggressive, substance use, and antisocial behaviors), both implicated in suicide risk (Verona & Javdani, 2011). Indeed, NEM is consistently linked to suicidality, since symptoms that maintain suicide risk, including general maladjustment, alienation from others, and difficulties managing distressing feelings, overlap with trait facets of NEM. Research shows that tendencies toward negative affect have been found to predict greater levels of hopelessness, which is the construct considered to be most closely associated with thoughts of suicide. And, heightened NEM has been associated with increased risk of suicide attempts (Useda, Duberstein, Conner, & Conwell, 2004).

Finally, the Constraint (CON) dimension may have particular utility in identifying individuals who are more likely to engage in suicidal behavior versus just ideation, especially under reactive or impulsive situations. Control, harm avoidance, and traditionalism are the comprising personality facets. Together, they measure impulsivity, fearlessness or risk-taking, and conformity to social norms. CON is particularly relevant to mental disorders and suicide risk due to its implications for behavior. Indeed, individuals lacking CON are risk-takers, lack self-control, and may act quickly in order to relieve stress. Perhaps consequently, low CON has been linked with externalizing psychopathology typified by difficulties with self-control and disruptive behavior (e.g. aggression), including substance abuse and antisocial personality disorder. These disorders are also linked with increased suicide risk, possibly since difficulties controlling behavior also underlie suicidal behavior. Indeed, low CON has been associated with nonsuicidal self-injurious behavior, which is thought to function for some individuals as a means of habituating to the pain and fear needed to engage in a suicide attempt (Joiner, 2005). It has also been associated with more lethal suicide attempts as well as death by suicide (Verona & Patrick, 2000).

Collectively, Tellegen's model of personality may be used to characterize certain aspects of suicide risk. Contemporary models of suicide (Joiner, 2005; Klonsky & May, 2015) stipulate that individuals who die by suicide require more than just the desire (e.g. feelings of low belongingness and high burdensomeness to others) but also the capability to

transition from desire to engaging in suicide. In contrast, individuals who are at risk of suicide, but are less likely to die by suicide, are thought to possess only desire. In the context of these models, it may be that individuals who comprise Apter's depressed suicidal subtype, displaying internalizing psychopathology, and a personality profile involving high Negative Emotionality (estrangement from others, stress reactivity) and low Positive Emotionality (low well-being, social closeness, and assertiveness), are more likely to primarily possess the desire for suicide. These individuals are particularly likely to consider suicide over a long period of time, with a small percentage meticulously planning and dying by suicide. Conversely, individuals who display primarily externalizing psychopathology, and high Negative Emotionality and low Constraint, essentially Apter's impulsive-aggressive subtype, may be more likely to possess the ability to engage in suicidal behavior if the desire is high enough at any particular moment (rather than persistent). It may be that individuals who are most at risk for a suicide attempt possess a combination of personality traits associated with desire and ability, exhibiting high Negative Emotionality, low Positive Emotionality, and low Constraint. In support of this conclusion, borderline personality disorder, psychopathology typified by high rates of suicidal behavior, reflects a similar conjunction of traits, at the cusp of both internalizing and externalizing psychopathology (Eaton et al., 2011).

Taken together, current research in personality and suicide indicates that there may be certain personality traits that characterize high risk for suicide, personality traits whose extreme expression may typify the link between psychopathology and suicide. Such work is of particular relevance to suicide prevention efforts. In particular, if personality traits could be used to identify clinically meaningful subgroups of individuals who are predisposed to greater suicide risk, such information could be used to tailor intervention strategies more closely to the needs of each suicidal subtype.

Burnout

Arnold B. Bakker[1] and Ana Isabel Sanz-Vergel[2]

[1] *Erasmus University Rotterdam*
[2] *Norwich Business School, University of East Anglia*

Introduction

It was in the 1970s when Freudenberger (1974) first used the term *burnout*. With this term, he wanted to describe the gradual emotional depletion and loss of motivation that he observed among volunteers working for aid organizations in New York. Although Freudenberger observed this phenomenon within a clinical context, after years of research, it has been shown that burnout may occur in any working context.

In the 1980s, Maslach and colleagues (1981) interviewed human services workers in California to find out how they handled stressful situations with clients. In the interviews, the workers often used the word *burnout* when explaining how they felt interacting with clients. However, they did not only show symptoms of emotional exhaustion but also reported a lack of professional competence and they endorsed a negative, callous attitude towards their clients. As a result, Maslach and her colleagues identified three core dimensions of burnout:

- Emotional exhaustion: feelings of being emotionally drained by one's contact with other people. This is the central strain dimension of burnout.
- Depersonalization/Cynicism: a negative or excessively detached response toward these people, who are the recipients of one's service or care.
- Lack of personal accomplishment: a decline in one's feelings of competence and successful achievement at work.

Nowadays, most scholars agree that exhaustion and cynicism are the core dimensions of job burnout. Personal accomplishment develops largely independent of the syndrome and is often excluded from the definition of burnout. Since burnout means that employees have lost the motivation and ability to invest effort in their work, research has confirmed that burnout is an important predictor of reduced performance, lower productivity, and reduced

client satisfaction. Moreover, burnout has a negative impact on employee well-being and psychological and physical health. It is therefore important to understand the possible causes of burnout. These causes are related not only to the characteristics of the work itself, but also to the way in which people experience their work and how they cope with difficult work situations. Therefore, the study of personality and individual differences is crucial to better understand the burnout syndrome.

Personality and Burnout

Personality characteristics are relatively stable aspects of the self that can help to explain why some individuals are more prone to experience burnout than others. Alarcon and colleagues conducted a meta-analysis in 2009 and after reviewing 114 samples they concluded that the environment is not the only predictor of burnout. They focused on the Big Five personality factors and found that all these factors were related to the different dimensions of burnout. Individuals high in emotional stability, extraversion, conscientiousness, and agreeableness were less likely to experience exhaustion, cynicism, and lack of personal accomplishment. Specifically, emotional stability was the most important predictor of exhaustion and depersonalization, whereas extraversion was the most important predictor of personal accomplishment. Finally, openness to experience was positively related only to one dimension of burnout (personal accomplishment). Beyond the Big Five, there are other personality factors that are also important to predict burnout. For example, optimism reduces the likelihood of experiencing feelings of exhaustion and to develop a negative attitude toward work (cynicism).

Therefore, regardless of the objective nature of the work environment, people tend to perceive their job favorably or unfavorably, depending on their personality. We can take as an example a specific work task: the submission of an important report. Individuals with low emotional stability may view this task as stressful and threatening, because these people have a tendency to experience unpleasant emotions such as anxiety or anger. However, individuals with high emotional stability may view the same task as challenging and motivating, because these people are usually calm and react favorably to demands. Apart from the perception of the environment as stressful or challenging, individuals may also differ in their ability to cope with job demands. Extraverts may be better able to cope with emotionally demanding situations, because they have the skills to use coping strategies such as seeking out social support and accepting help from others. Personality is indeed reliably related to burnout.

Swider and Zimmerman (2010) used meta-analytic path modeling to investigate the relationships between Five-Factor Model personality traits and job burnout. Their results were consistent with those of Alarcon, and showed that neuroticism (positive) and extraversion (negative) were the most important predictors of emotional exhaustion, whereas agreeableness was the most important predictor of depersonalization (negative). Conscientiousness and openness hardly explained any meaningful and unique variance in burnout. Furthermore, they found that job burnout partially mediated the relationships between Five Factor Model personality traits and personnel turnover and job performance, while fully mediating the relationships with absenteeism.

Job Demands and Resources

The Job Demands-Resources theory developed by Bakker and Demerouti (2014; Demerouti, Bakker, Nachreiner & Schaufeli, 2001) proposes that burnout is the result of a suboptimal work environment in which the job demands are too high, and job resources are too low. Job demands are aspects of the job that require sustained physical, emotional, or cognitive effort. Repeated confrontation with a high workload and emotionally challenging client interactions is draining and results in high levels of exhaustion. Job resources are the physical, psychological, social, or organizational aspects of the job that help to achieve work goals, reduce job demands and the associated physiological and psychological costs, or stimulate personal growth, learning, and development. Resources such as support, feedback, task variety, and autonomy can be used to deal with high job demands, and are also motivating in themselves. Employees who have access to an abundance of job resources are typically engaged in their work and have a positive, enthusiastic attitude toward work. However, when important job resources are missing, employees may develop negative attitudes toward work (cynicism).

Thus, the combination of high demands and low resources is an important predictor of burnout. This means that work environments can be designed such that the risk of burnout is limited. For example, in 2005, Bakker, Demerouti, and Euwema conducted a study among teachers who experienced job demands such as overload or work-home interference. These teachers did not experience burnout when they had access to job resources such as autonomy or social support. However, as discussed above, not only job demands and job resources interact in predicting burnout – personality also plays an important role.

Personality versus Environment

Since personality influences how employees perceive, select, and manage their work environment, it can be argued that personality factors interact with job demands and resources in predicting burnout. For example, since extravert individuals like to meet other people, they become socially competent and may be better able to deal with high emotional job demands. Their social competence will also help them to mobilize their social job resources (e.g. social support, performance feedback, coaching, recognition), which they can then use to deal with their job demands. Only a few studies have examined the interplay between personality and the work environment (i.e. job demands and resources). Bakker and his colleagues (2006) found that volunteer counselors low in neuroticism were hardly influenced by negative interactions with clients, whereas those high in neuroticism reported higher levels of exhaustion and depersonalization after negative interactions with clients.

Extravert employees may also be better able to mobilize their job resources. Because extraversion is characterized by a tendency to be self-confident and to have frequent and intense personal interactions, extraverts are more likely to craft their social resources, i.e. take the personal initiative to ask for help and feedback. Indeed, Bipp and Demerouti (2014) found that employees scoring high on approach temperament were more likely to seek job resources in their work environment such as opportunities for development and

social support. Such resources can be used to protect oneself against the impact of high job demands, and thus avoid burnout. Future research should more explicitly investigate the interplay between personality, job demands, and resources.

Future Directions in Burnout Research

Bakker and Costa (2014) have recently argued that burnout may be the result of an accumulation of job demands and strain over time, whereby employees at risk of burnout start to make mistakes and create problems that further add to the already high job demands. They refer to self-undermining – a consistent pattern of undesirable behaviors in the workplace that undermine job performance. Self-undermining may be the consequence of high levels of job strain, and be the fuel of a loss cycle of high job demands and burnout. Future research should try to measure such behaviors and investigate whether self-undermining is an important behavioral predictor of burnout.

Recent research has indicated that burnout may be a slow process of daily symptoms of exhaustion and cynicism that may fluctuate over time. Xanthopoulou and Meier (2014) argue that levels of exhaustion and cynicism may vary from day to day, depending on the daily work characteristics. Exhaustion may also be the consequence of certain performance episodes during which employees need to deal with complex and highly demanding tasks with little resources available – for example, a performance episode that consists of a long business meeting with tough negotiations with clients. It is conceivable that repeated confrontation with such performance episodes leads to an accumulation of short-term fatigue, which may eventually translate into chronic exhaustion and cynicism (i.e. burnout).

Future research may also focus on job crafting as a possible means of preventing and reducing burnout. Recent studies have produced some promising results, suggesting that employees can be trained to engage in job crafting – to proactively optimize their own job demands and resources. Job crafting improves the fit between the individual employee and his/her environment, reduces burnout, and facilitates work engagement and job performance. It would be interesting to find out whether such job crafting interventions are also effective among individuals who already suffer from high (clinical) levels of burnout. Finally, it is important to take into account the role of recovery from work-related stress. In her paper on "Strategies to Prevent Burnout," Demerouti (2015) highlights that psychological detachment, engaging in relaxing activities, or engaging in activities with family and friends are all crucial strategies that can reduce symptoms of burnout.

Religiosity and Spirituality

Jack L. Powell

University of Hartford

Pervasiveness of Religiosity and Spirituality

The vast majority of people in the United States and around the world identify themselves as religious and/or spiritual, and many of these individuals consider these beliefs to be some of the most important that they hold. Across the world, 5.8 billion people identify with a religious group. This represents 84% of the world population. In the United States, 83% believe in God, 77% say religion is important in their life, 72% report that they attend religious services at least a few times a year, and 72% believe in heaven. While these percentages have gone down over the past several years, the percentage of people who say they often feel a deep sense of spiritual peace and well-being as well as a deep sense of wonder about the universe has risen. The phrase "spiritual but not religious" has increasingly become a way that individuals describe themselves.

Historical Treatment of Religiosity and Spirituality

It should not be surprising, then, that researchers have increasingly turned their attention to religiosity and spirituality (R/S) and the roles they may play in individuals' physical, social, and mental health.

Some of psychology's leading figures and early pioneers addressed issues of R/S. William James used his phenomenological approach to describe some of the more extreme forms of religious experience. Sigmund Freud wrote several papers on the irrational bases of religious beliefs and the neurotic influences of those beliefs on the individual. Freud's student, Carl Jung, had a much more favorable view of religion, arguing that religion fulfilled a basic human need.

For the next several decades, however, psychologists shied away from the study of R/S. Researchers in psychology believed that human behavior could be understood through psychological accounts (e.g. biology, reinforcement, unconscious influences) and that

religious accounts were unnecessary. Additionally, they wanted their up-and-coming field to be modeled after "harder" sciences like physics and not associated with "softer" fields like philosophy and religion. At the same time, religious professionals were threatened by the negative portrayals of religion by Freud and Behaviorists, among others, as well as the competition from clinical psychology that was increasingly challenging their role as counselors for individuals who needed support and guidance.

For multiple reasons, the psychological study of R/S reemerged toward the end of the twentieth century and continues to this day. First, lay people have become more interested in R/S. This extends beyond interest in their own religion to other religions, to spirituality more generally, and to the role of religion in health and well-being. Second, psychology has become more secure as a science and, consequently, less concerned that studying R/S would be viewed negatively. Third, psychology has become more interested in addressing practical questions about the needs of individuals. The role of R/S in health and well-being quickly became the most researched question in the field.

Defining Religiosity and Spirituality

As researchers have increasingly turned their attention to R/S, one of the major points of confusion and debate is how to define these basic terms. Most researchers use the terms "sacred" and "transcendent" to distinguish religious and spiritual behavior and beliefs from secular beliefs; that is, religiosity and spirituality involve a search for or belief in the divinity, higher power, or that which is beyond the merely physical human experience or material universe.

With the increasing secularization in Western culture and as individuals increasingly identify themselves as spiritual but not religious, greater distinctions are being made between the terms, religiosity and spirituality. Although both researchers and the general public tend to agree there is significant overlap between them, one common distinction is that the former is located in an institutional framework while the latter is more personal or internal. Religion consists of an organized system of beliefs, practices, and symbols and is derived from established traditions. There is less agreement on defining spirituality. Spirituality more often refers to those who are personally seeking the transcendent or sacred. In US surveys, the majority of individuals consider themselves to be both religious and spiritual, while a significant minority identify as either religious, spiritual, or neither.

Measuring Religiosity and Spirituality

There is no "measure" of religiosity or spirituality. There are, however, measures of specific R/S behaviors (e.g. frequency of attending religious services and how often one prays), feelings (e.g. fear, awe, guilt, and disgust), and cognitions (e.g. belief in deity, belief in afterlife, and values). Many of these measures rely on self-report and can be determined by answers to simple multiple-choice questions asking individuals about their religious membership, affiliation, attendance, experiences, knowledge, etc.

Increasingly, scales have been developed to measure one or more dimensions of R/S. Over a hundred such scales have been used in research and subsequent studies have attempted to reduce these measures to a handful of categories. One of the earliest and still most frequently used measure of R/S is the religious orientation scale. Individuals who score high on Intrinsic Orientation consider their faith to be their master motive in life. They incorporate their religious teachings and values into their lives, and are less likely to compromise them; these individuals "live" their faith. A sample Intrinsic Orientation item is: "I try hard to carry my religion over into all my other dealings in life."

Individuals who score high on Extrinsic Orientation are more likely to "use" their religion, their involvement in religion is motivated by nonreligious factors, and religious teachings and values are only adopted to the extent they suit the person's own purposes. A sample Extrinsic Orientation item is: "Occasionally I find it necessary to compromise my religious beliefs in order to protect my social and economic well-being."

Individuals who score high on the religion as quest orientation have an open-ended and open-minded approach to R/S matters and they are more interested in the search for and struggle with existential questions than they are in arriving at clear answers to R/S issues. A sample Religion as Quest item is: "Questions are far more central to my religious experience than are answers."

Religiosity, Spirituality, and Health

Research shows that the great majority of individuals in the United States and around the world look to religion and spirituality to help them cope with their mental or physical concerns. And every major religion provides beliefs and rituals to help individuals deal with the many stresses and challenges of life. R/S involvement can facilitate coping in numerous ways: providing a positive worldview, meaning and purpose, hope, empowerment, role models for suffering, forgiveness, guidance for decision-making, and social support.

Whether R/S involvement helps or hurts an individual's efforts to deal with stress or trauma may depend on the type of religious coping the individual employs. Three religious approaches to coping have been suggested. In self-directing coping, individuals rely on their God-given resources and free will to solve the problem on their own; in deferring coping, people passively defer the responsibility for problem solving to God; and in collaborative coping, people work together with God as partners in the problem-solving process. The collaborative approach to coping is generally considered to be the most positive style and the one to produce the most positive outcomes of negative events.

Individuals report that they use R/S involvement to help them cope with trauma, stress, and life difficulties. The question remains whether it can be empirically demonstrated that R/S involvement is associated with mental and physical health. Hundreds of studies have been conducted over the past few decades exploring the possible effects of R/S activities and involvement on mental and physical health. Because of the increased quantity and quality of these studies, researchers no longer ask whether there is a relationship between R/S involvement and health, but rather, look at more specific questions such as what aspects of health (mental/physical) are most likely to be affected by R/S involvement and what aspects of R/S involvement are responsible for its effects on health.

There are many ways to conceptualize physical health, but certainly one important outcome measure is life expectancy. Over a hundred studies have examined the relationship between R/S involvement and mortality and the majority of studies have found that R/S predicted greater longevity. However, the R/S effect is not the same across all groups of people and all types of R/S involvement. Specifically, it is religious attendance (more than private R/S activity or beliefs) that is most associated with longevity; and the R/S effect is greater in women those in poor health, those with minority status, and those with low educational attainment. In putting the size of the R/S effect on longevity in the context of standard treatments used in medicine today, it is similar in magnitude to the effect that exercise-based cardiac rehabilitation or cholesterol-lowering drugs have on reduction in mortality.

There is strong research support, then, for concluding that R/S involvement is associated with longer life expectancy. There are likely three avenues through which R/S involvement exerts this effect: psychological, social, and behavioral. Regarding psychological mediators, greater R/S involvement is associated with a number of positive psychological traits such as forgiveness, volunteering, gratefulness, optimism, hope, meaning and purpose, self-esteem, and sense of control. R/S involvement is also negatively correlated with several negative psychological traits such as loneliness, depression, and anxiety. Regarding social mediators, individuals with greater R/S involvement report more social support and greater marital stability. Finally, regarding behavioral mediators, individuals with higher R/S involvement are more likely to exercise, visit dentists, volunteer, wear seat belts, and eat healthier; they are also less likely to smoke, drink, take recreational drugs, and engage in accident-prone behavior.

Personality

Personality refers to an individual's characteristic ways of thinking, feeling, and behaving. The most widely used conceptualization of personality is the five-factor trait model, also known as the Big Five that comprises five underlying personality dimensions (McCrae & Costa, 2003). These include extraversion, which refers to sociability, positive emotionality, and energy; neuroticism, which concerns emotional instability, and distress in response to stressors; agreeableness, which implies trustfulness, altruism, and cooperativeness; conscientiousness, which reflects purposeful striving toward goals, persistence, self-control, and planning; and openness to experience, which involves curiosity, flexibility, appreciation of personal emotion, and imaginativeness. These five personality dimensions are key determinants of interpersonal and intrapersonal characteristics and behavior, including a variety of positive psychological characteristics.

Positive Psychology and Positive Psychological Characteristics

The positive psychology approach posits that positive characteristics are more than the absence of negative characteristics and independently contribute to a variety of positive life outcomes. Several dispositional positive psychological characteristics are linked to the Big Five personality factors. Research has found that individuals with more outgoing and positive personalities generally experience and report greater positive psychological characteristics compared with individuals endorsing more negative personality dimensions. We provide an overview of a range of positive psychological characteristics associated with the Big Five personality in the following sections.

The Big Five and Well-Being

Research on well-being illustrates two different traditions of well-being: hedonic and eudaimonic. Subjective well-being and psychological well-being are phrases frequently used as being synonymous with hedonic and eudaimonic well-being indices, respectively (Ryan & Deci, 2001). Subjective well-being stems from the experience of high positive affect, low negative affect, and high satisfaction with life, that is, judgments about the good or bad events in life. Meta-analytic studies have found that extraversion, conscientiousness, and openness to experience were related to greater positive affect; whereas neuroticism was the strongest predictor of negative affect and less positive affect (Steel, Schmidt, & Shultz, 2008).

On the other hand, eudaimonia conceptualizes psychological well-being as occurring when a person's life activities are congruent with his/her values and the individual is holistically or fully engaged. Six distinct aspects of psychological well-being are autonomy, personal growth, purpose in life, environmental mastery, positive relatedness, and self-acceptance. Research has shown that extraversion and agreeableness were associated with greater overall psychological well-being, whereas neuroticism was related to lower levels of overall psychological well-being (Koko, Tolvanen, & Pulkkinen, 2013).

The Big Five and Positive Traits Described as the "HERO" Within

Four positive psychological characteristics of hope, efficacy, resilience, and optimism (HERO) make up the psychological capital. Hope encompasses the belief in one's ability to achieve personal goals and consists of two related but distinct cognitive components of pathways (planning to meet goals) and agency (goal-directed action). It is conceptualized and assessed as both a dispositonal trait and a state. Research has shown that extraversion, conscientiousness, agreeableness, and openness traits were related to greater dispositional hope, and neuroticism was negatively associated with dispositional hope (Hutz, Midgett, Pacico, Bastianello, & Zanon, 2014).

Efficacy is the belief that one is competent in dealing with life challenges. Research has shown that extraversion, agreeableness, conscientiousness, and openness traits were associated with greater self-efficacy; and neuroticism was related to less self-efficacy (Wang et al., 2014).

Resilience is the ability to bounce back from adversity and stressful or challenging experiences. Research has shown extraversion, agreeableness, conscientiousness, and openness to experience were related to greater resilience; neuroticism was negatively associated with resilience (Fayombo, 2010).

Optimism is a generalized positive outlook and involves individuals having favorable expectations for their future, and is conceptualized and measured as a trait and state that can be learned and developed. Significant positive relationships between extraversion, conscientiousness, agreeableness, and openness traits and dispositional hope and negative association of neuroticism with dispositional hope have been empirically demonstrated (Hutz et al., 2014).

The Big Five and Trait Emotional Intelligence

Emotional intelligence is an adaptive emotional functioning and consists of interrelated emotional competencies related to perception, understanding, utilizing, and managing emotions in the self and others. Emotional intelligence is defined and assessed both as an ability and as a trait or typical functioning. Research has shown personality factors to be associated with trait emotional intelligence, with neuroticism as the strongest correlate of low trait emotional intelligence, followed by extraversion, conscientiousness, agreeableness, and openness as correlates of high trait emotional intelligence (Petrides, Vernon, Schermer, Lighart, Boomsma, & Veselka, 2010).

The Big Five and Gratitude

Dispositional gratitude consists of noticing and appreciating the positive in life and being thankful for these positive aspects of life. Overall, gratitude was positively correlated with certain facets from the extraversion, openness, agreeableness, and conscientiousness domains, and negatively correlated with certain neuroticism facets (Wood, Joseph, & Maltby, 2009).

The Big Five and Self-Compassion

Self-compassion entails an accepting stance toward oneself and those aspects of one's life that are disliked and criticized. Greater self-compassion is related to more agreeableness, extraversion and conscientiousness, and less neuroticism (Neff, Rude, & Kirkpatrick, 2007).

The Big Five and Grit

Grit is an individual difference characteristic that consists of focus and perseverance toward goals and was found to be associated with conscientiousness (Rimfeld, Kovas, Dale, & Plomin, 2016).

The Big Five and Mindfulness

Mindfulness consists of a nonjudgmental focus on the present and can be a trait as well as state. Research suggests neuroticism and conscientiousness as the two strongest correlates of trait mindfulness, and mindfulness practice to be positively related to extraversion and openness, and negatively associated with neuroticism (Giluk, 2009; van den Hurk et al., 2011).

The Big Five and Character Strengths

Character strengths are clusters of personality features that are morally valued and contribute to good character. These trait-like strengths can be divided into categories of wisdom, courage, humanity, justice, temperance and transcendence. Macdonald, Bore, & Munro (2008)

found that an overall higher level of character strengths in these categories was associated with more agreeableness, conscientiousness, extroversion and openness, and less neuroticism.

The Big Five and Positive Social Influence

Social scientists are also interested in investigating the ways of positively influencing people's attitudes and actions. Cialdini (2001) proposed six principles of persuasion of authority, consensus, commitment, scarcity, liking, and reciprocity. The first principle of *authority* is considered a form of social influence and posits that people are inclined to follow suggestions and recommendations from a person in authority. The principle of consensus or social proof is asserted to operate when individuals observe multiple others displaying the same behavior or belief, which leads that person to behave similarly. The principle of commitment refers to the notion that people strive to maintain consistent beliefs and act in accordance with those beliefs. The principle of scarcity increases the perceived value of products and opportunities. Liking strategy asserts that people tend to say "yes" to people they like, thus, when a request is made by a person we like, we are much more inclined to act accordingly. Finally, the principle of reciprocity indicates that people tend to be inclined to return a favor and go to a great deal of effort to do so. The possibility of developing positive persuasive messages takes into account the target person(s) and how they behave.

Alkis and Temizel (2015) found that people who are more agreeable tend to be persuaded by people they like, whereas people who are more conscientiousness tend to be persuaded by people in authority. Agreeableness tends to be the most susceptible personality trait to persuasion strategies, whereas openness is the least susceptible personality trait to persuasion strategies. Extraversion and neuroticism personality traits tend to be susceptible to scarcity strategy; and, except openness, all personality traits tend to be susceptible to reciprocation strategy. Therefore, knowing specific personality profiles can help in personalization of persuasion strategies for maximum effectiveness.

Overall Patterns between the Big Five Personality Traits and Positive Psychology Characteristics

Although there are some differences in the relationship of the Big Five traits with specific positive psychology characteristics, in general a Big Five trait pattern of high extraversion, high agreeableness, high conscientiousness, high openness, and low neuroticism describes the connections between the Big Five and positive functioning. This constellation of the Big Five and positive psychology characteristics might underpin the adaptive and growth functioning.

Hope

Kevin L. Rand and Ian C. Fischer

Indiana University–Purdue University

Hope, the belief that what is desired can be attained, is a defining characteristic of the human psyche. One of the oldest accounts of hope is the Greek myth of Pandora. According to legend, Zeus sent Pandora to Earth to exact revenge on mortals for receiving fire from Prometheus. He gave her a dowry jar, instructing her never to open it. Unable to resist temptation, Pandora opened the jar and unwittingly unleashed suffering into the world. She rushed to close the lid, not noticing that hope was stuck inside. It is unclear from the myth if hope was intended to be another scourge or a gift.

Historically, opinions about hope have been mixed. Plato, Bacon, and Nietzsche expressed decidedly negative views of hope, considering it a delusion that merely protracts human suffering. In contrast, writers such as Martin Luther and Emily Dickinson lauded hope as the engine that drives human striving, particularly when life is difficult.

In the twentieth century, scholars became interested in hope. Many physicians argued that positive psychological experiences, including hope, affected the body's healing process and therefore merited scientific investigation. Initially, there were differing conceptualizations of hope, with some scholars defining it as an emotion and others as a positive expectation. By the 1950s, there was general consensus that hope involved the expectation that goals could be achieved in the future. This conceptualization was consistent with emerging psychological theories of human motivation, including expectancy-value theory.

In the 1970s, psychologist C. R. Snyder became interested in hope via his studies on excuse-making. Snyder's research elucidated the process by which people distanced themselves from their failures. During post-experiment conversations, however, participants commented that making excuses was only part of how they navigated the world; they also strived to move closer to things they wanted. This sparked Snyder's interest in how people pursued goals, and in the 1980s he took a sabbatical to study this process. Snyder interviewed people about their goal-related thoughts. People consistently mentioned two interacting processes: thinking of routes to reach their goals and motivating themselves to use those routes.

Based on these conversations, Snyder defined hope as the perceived ability to achieve desired goals. As detailed in his book, *The Psychology of Hope* (Snyder, 1994), this conceptualization comprises three cognitive elements: goals, pathways, and agency. *Goals* are desired future states that serve as mental targets to guide behavior. They can manifest as self-talk or mental images. Goals vary along several dimensions, including: time-frame, importance, difficulty, and specificity. Goals can be framed positively (e.g. "I want to go to law school") or negatively (e.g. "I don't want to get sick"). For hope to be relevant, Snyder posited that goals had to have an intermediate level of uncertainty. Goals certain to be achieved require no hope; whereas, impossible goals are not likely to influence behavior.

Pathways is the perceived ability to generate strategies or routes connecting the present to a desired future goal. The ability to create multiple routes is important when barriers are encountered. *Agency* is the perceived ability to motivate oneself to use pathways to reach a goal. It is often manifested as positive self-talk (e.g. "I can do this!"). Agency is important when people experience setbacks because it enables them to generate the motivation to use an alternative pathway to their goal.

During a goal pursuit, pathways thinking gives rise to greater agency, which leads to more pathways thinking. This transactional thought process can create an "upward spiral," wherein someone beginning a goal-pursuit experiences some success, leading to increased thoughts about other routes to success and the ability to motivate oneself to use those routes. Although positively correlated, pathways and agency are separate processes, and it is possible for people to be high in one and low in the other.

Snyder's model of hope emphasizes thoughts rather than emotions. Emotions are merely consequences of the goal-pursuit process. Experiencing setbacks leads to negative emotions (e.g. frustration); whereas, making progress leads to positive emotions (e.g. joy). Hope is considered a learned trait. Pathways thinking develops as an infant begins to make associations between co-occurring events. Around 12 months of age, the emerging sense of self (i.e. psychological birth) marks the beginning of agency. During this time, children begin to understand they can influence the world around them, and early goal pursuits establish the foundation of later hope. If childhood is characterized by goal accomplishments and overcoming obstacles, then a hopeful mindset develops. In contrast, if childhood is marked by repeated failures or the lack of attainable goals, then a lower-hope baseline is established.

A criticism of Snyder's hope theory is that it is conceptually and empirically similar to another personality trait: optimism. Hope and optimism both involve positive expectations about the future. However, an important distinction is that hope focuses on what a person can do to achieve desired goals. In contrast, optimism is a general expectation that good things will happen, regardless of one's control over them. A student can hope to be valedictorian of her class, but can only be optimistic that it won't rain on her graduation day.

When studied together, hope and optimism have been shown to be empirically distinct and predict different outcomes. Hope predicts controllable processes useful for working toward personal goals (e.g. tolerating pain); whereas, optimism does not. Similarly, hope predicts goal-focused achievement such as academic performance; whereas, optimism does not. Hope and optimism also differentially relate to aspects of psychological

well-being. Hope is more strongly associated with a sense of control, purpose, and growth (i.e. eudaimonic well-being) than optimism. In contrast, optimism is more strongly associated with the presence of positive emotions and the absence of negative emotions (i.e. hedonic well-being) than hope.

Measuring Hope

The most widely used measure of hope is the adult Trait Hope Scale (Snyder et al., 1991). This 12-item instrument measures pathways (e.g. "I can think of many ways to get out of a jam") and agency (e.g. "I energetically pursue my goals"). Higher scores indicate greater hope. Research has shown it to have good internal consistency and test-retest reliability. Consistent with Snyder's theory, factor-analytic studies have shown the Trait Hope Scale consists of two correlated factors (i.e. pathways and agency) driven by an overarching hope factor, and that this structure is the same in women and men.

The Children's Hope Scale is a measure for children ages 8 to 16 years. It consists of three pathways and three agency items. The State Hope Scale is a six-item measure to assess people's hopeful thinking "right now." Research has shown both scales to have good internal reliability, a factor structure similar to the Trait Hope Scale, as well as convergent and discriminant validity.

Hope occurs at various levels of specificity, and there are instruments to measure more specific hope. The Domain-Specific Hope Scale measures hope in six life domains: social relationships, romantic relationships, family life, academics, work, and leisure activities. The Goal-Specific Hope Scale assesses hope for a particular goal and has been shown to predict goal progress above and beyond trait hope levels.

Research on Hope

Hope consistently predicts goal-directed performance and overall well-being. Higher hope predicts better student performance at all levels of education, from primary to post-graduate, even after controlling for ability and previous achievement. A six-year longitudinal study published in the *Journal of Educational Psychology* (Snyder et al., 2002) found that student hope, measured at the start of the first semester of college, predicted higher cumulative grade point averages, lower drop-out rates, and higher graduation rates, even after controlling for intelligence, high school grade point averages, and college entrance exam scores. In a study of Division I track athletes, higher hope predicted better athletic performance, even after controlling for innate athletic ability.

Hope is a strong predictor of psychological well-being. Greater hope is associated with more positive thoughts, greater positive affect, greater self-worth, fewer negative thoughts, and fewer negative emotional experiences, including lower levels of depression and anxiety. A longitudinal study found that initial levels of hope predicted subsequent levels of anxiety and depression in college students, but that anxiety and depression did not predict subsequent hope. This suggests that hope is not simply an artifact of feeling better, but instead is a driver of psychological well-being.

Hope appears to have salubrious influences on physical health as well. Higher-hope women have greater knowledge about cancer and stronger intentions to engage in screening and prevention efforts than their lower-hope counterparts, even when controlling for intelligence and previous experience with cancer. Similarly, higher-hope primary care patients engage in more exercise and have healthier diets than their lower-hope peers. Even after succumbing to physical illness, hope confers benefits. Among survivors of childhood cancers, hope predicts greater post-traumatic growth and less negative rumination. Higher hope predicts more adaptive coping and faster recovery from burns, spinal cord injuries, arthritis, fibromyalgia, multiple sclerosis, and blindness.

Applications of Hope Theory

Given the positive associations between hope and life outcomes, interventions have been developed to increase hopeful thinking. A newly developed classroom intervention for college athletes consists of goal-setting, small group activities, journaling, and active learning demonstrations. Early research found this intervention increased trait hope, confidence, self-esteem, and coach-rated athletic performance. Other classroom interventions have been shown to increase hope, purpose in life, self-worth, vocational calling, specific goal progress, and academic achievement among middle-school and college students. Hope-based treatments among community populations have shown promise in reducing anxiety, depression, and hopelessness, while improving hope, social functioning, self-esteem, and meaning in life.

Future Directions

Hope is a useful construct for understanding achievement and well-being in a variety of situations, but several issues merit further investigation. For example, there may be circumstances where hope is maladaptive. One provocative possibility is that hope may increase suffering among people with terminal illnesses, particularly cancer. There is accumulating evidence that the dogged pursuit of survival or cure among advanced cancer patients is associated with worse psychological outcomes for patients and their families without any meaningful improvement in survival. Further research is needed to understand if "false hope" is involved in this process.

As research on hope expands, it is important to understand if hope functions similarly in different groups and cultures. To date, there is no evidence of racial or gender differences in the structure or mean levels of hope. However, there are group differences in achievement and well-being. It remains unclear how groups with similar levels of hope can have such disparate outcomes. One possibility is that hope has different influences on coping across groups. For example, research suggests that hope weakens the relationship between depressive symptoms and suicidality among Caucasian and Hispanic people, but not among African Americans.

Another promising area for future work is the application of hope theory to intergroup conflict. To the extent that such conflict is a function of different groups pursuing similar

goals, research on hope may provide insight into how to reduce goal-related frustration and increase achievement and well-being.

Forgiveness

Robert D. Enright

University of Wisconsin– Madison and International Forgiveness Institute, Inc. Madison, Wisconsin

Forgiveness within psychotherapy is a new and empirically verified form of treatment for clients who present with unhealthy emotions and moods resulting from unjust treatment by others. The focus in this newly emerging area is on the client forgiving others rather than on seeking forgiveness from or apologizing to others. Forgiveness therapy is a way of reducing resentment and related negative psychological conditions such as anxiety, depression, and low self-esteem. Although it is common in publications for authors to state that there is no agreed-upon definition of forgiveness, there is an emerging consensus in psychology that the definition of forgiveness includes these three themes: first, the client experienced unfair treatment from one or more people. The focus is interpersonal and does not include psychological injury from, for example, natural disasters such as hurricanes or earthquakes. Second, the forgiver makes a commitment to reduce resentment specifically toward the one who acted unjustly. This can take time and often is a struggle to do so. Third, over time, the forgiver works on offering goodness of some kind toward the injuring person. This third component of the definition is added because forgiveness is seen as a virtue, a response of goodness toward the injuring person and this can take the form of respect, compassion, and even love toward the injuring person. In forgiveness therapy, a client need not reach the pinnacle of forgiveness such as offering unconditional love toward the one who injures. Simply making progress toward reducing resentment and offering small amounts of goodness can be therapeutically beneficial.

Forgiving others often starts as a cognitive insight that one can not only strive for fairness when hurt by others but also offer mercy on another person or going beyond justice. Mercy includes this sense of compassion on the other, not because of what he or she did, but in spite of this.

Some clients make the mistake of thinking that if they forgive, then they cannot seek justice. They see these as mutually exclusive. This is a mistake that the helping professional should gently correct. Otherwise, a client might conclude that upon forgiving a person who is continuously abusive, then that client has an obligation to enter once again into the hurtful relationship. To forgive and to reconcile are not the same. Reconciliation is a

negotiation strategy in which two or more people come together again in mutual trust. One can forgive and not reconcile if the other remains a danger to the one who forgives. The offer of forgiveness can be unconditional, offered whether or not the other person feels remorse or apologizes. Reconciliation, on the other hand, is always conditional on trust being demonstrated and restored. To forgive is not to condone or excuse the other's unjust behavior. Instead, the forgiver acknowledges the wrongdoing of the other and decides to offer goodness in the form of mercy nonetheless.

Forgiveness is more than reducing resentment toward the other person(s). One can cease resenting the other by condemning that person, thinking that he or she is not worthy of the effort to offer goodness. In trying to understand forgiveness, some people confuse what forgiveness *is* (a response of reduced resentment and the offer of goodness toward those who acted unjustly) with the psychotherapeutic *outcomes* of the forgiveness process (improved client health, which can include both psychological and physical aspects). The paradox of forgiveness, shown through scientific studies, is that as this goodness is extended to the other(s), it is the forgiver who experiences considerable psychological benefits, which can last after psychotherapy ends.

The first empirically based article on person-to-person forgiving was published in the *Journal of Adolescence* in 1989. The focus was an extension of the work on the psychology of justice pioneered by Jean Piaget in the 1930s and Lawrence Kohlberg in the late 1960s through the mid-1980s. Basing this new forgiveness work on these pioneering efforts in developmental psychology, the authors Enright, Santos, and Al-Mabuk focused on the increasing cognitive complexity of how children, adolescents, and adults think about forgiveness, particularly what conditions need to be met before the participant will offer forgiveness. Children confused forgiveness with revenge (If I can hit the one who hit me, then I can forgive) or compensation (If the other gives back what is taken, then I can forgive), thus not only distorting forgiveness but rendering it conditional on others' responses to the forgiver. Only in adulthood was there a clear indication that to forgive is a free choice that could be offered regardless of the offending person's response or lack of response. That choice includes the beneficence of compassion for the other as an end in and of itself. Helping professionals need to explore clients' thinking about what forgiveness is and is not prior to commencing forgiveness therapy because misconceptions are quite common especially in people who have not given much thought to the topic of forgiveness.

Forgiveness therapy (FT) is the deliberate attempt on the client's part to reduce resentment and offer goodness to the person(s) who acted unjustly toward the client. The first empirical study of FT was done by Hebl and Enright in 1993 in which elderly women forgave family members for a variety of injustices. There are at least seven assumptions of forgiveness therapy: (1) in contrast to other forms of therapy that refrain from value judgements, FT assumes that there is right and wrong and the client upon careful reflection can label another's actions as morally wrong or unjust; (2) unlike traditional forms of therapy, FT's focus is more on the offending other than it is on the client's internal emotional reactions and behaviors; (3) FT assumes that a merciful focus on the offending other person can be therapeutically beneficial to the clients because in the act of merciful giving is the insight that one is stronger than at first thought; (4) A client need not become a perfect forgiver to derive psychological benefit. In fact, in research with incest survivors by Freedman and Enright, at the end of treatment, the participants reached

only an average degree of forgiving the offending person, yet went from clinically depressed to nondepressed; (5) FT as a process takes time and should not be rushed; (6) FT can reduce and even eliminate unhealthy anger in the long term. This is hypothesized because FT focuses on the *cause* of emotional disruption (in the case of FT, unjust treatment by others) and not just on the effects (the presenting symptoms). By addressing how the client responds to the cause (and particularly to the one who generated that cause) through FT, the symptoms are reduced; (7) even when unhealthy anger is reduced or eliminated, the client still may feel angry from time to time. This is normal and he or she should not be overly concerned as long as the client now is in control of the anger rather than the toxic anger controlling him or her.

At present, there are two FT models that have considerable empirical support, one by Enright and one by Worthington. Common to these approaches are: (1) identifying the person and the event(s) of injustice; (2) examining how the injustice has led to psychological compromise in the client (so that he or she can work on ameliorating the symptoms); (3) knowing what forgiveness is and is not; (4) working toward understanding the offender(s) by taking larger perspectives beyond the unjust even. This can include seeing the offending person's weaknesses or confusions, not to excuse but to better understand him or her; (5) cultivating empathy and/or compassion toward the offending person; and (6) being aware of positive change in the self and persevering in the process of forgiveness over time.

A key component to FT is cognitive, specifically to help the client understand the inherent (built-in) worth of all people, which also includes those who offend others. This leads to the conclusion in clients that even those who act unjustly toward the client have inherent worth. These insights can take weeks or months to develop in clients. A further development in FT is clients concluding that they, too, possess inherent worth. It is at this point in psychotherapy that clients begin to improve in their psychological health, including enhanced self-esteem.

Self-forgiveness is a process that many clients request. Self-forgiveness can follow the same process of FT toward offending others with one important addition: the one who is self-forgiving should consider going to those who were offended by the client's actions and seek forgiveness from them and make amends where appropriate. Self-forgiveness is described in detail in the book, *8 Keys to Forgiveness*.

A meta-analysis of 54 empirical studies of FT, specifically focused on the Enright and Worthington FT approaches, reported statistically significant improvements in forgiveness and hope and significant decreases in anxiety and depression for clients who were randomly assigned to FT compared to those assigned to either no-contact or active control groups. The longer the duration of FT, the better the psychological outcomes for the clients. Another meta-analysis done in 2004 concluded that one-on-one individual FT produces stronger results than group FT. Follow-up analyses (after treatment has ended) show that clients who have engaged in FT tend to maintain the improvements in psychological health.

As a way to introduce forgiveness to children and adolescents, forgiveness education has been developed by the Enright research group. Curriculum guides for teachers who serve students from age 4 through age 18 have been devised. The gist of these guides, for teachers, social workers, and school counselors, is to aid children in their developmental understanding and practice of forgiveness through picture books and novels for youth. As the students see story characters experiencing injustice and then forgiving, the students then

have models that help them to explore forgiveness in nonthreatening situations. For example, for 6-year-olds, the students are introduced to the Dr. Seuss story, *The Sneetches*, in which a community begins to exercise feelings of superiority because of the number of stars that they wear on their shirts. The point of the story is to show that people should not be judged by status but instead by their shared inherent worth as persons. This theme can be extended educationally to the idea that even those who act unfairly have inherent worth. Research shows that as children are introduced to forgiveness for even one hour per week for about 12 weeks, then statistically significant reductions in anger and increases in academic achievement can occur. These programs have been researched in Belfast, Northern Ireland, a central-city in the United States, and Seoul, Korea.

Gratitude

Alexis T. Franzese and Carolina P. Seigler

Elon University

Gratitude is the quality of being thankful. Gratitude can also be described as a feeling of appreciation or thanks, or an expression given in response to kindness, blessing, or fortune. The term "gratitude" traces its origins back to the Latin word *gratus,* the root of which (*grat-*) means pleasing or thankful.

One of the leading researchers on gratitude, Richard Emmons, posits that gratitude has two key components – the personal and the societal. As a personal practice, gratitude may simultaneously lead to both individual, personal health benefits, and a greater sense of social belonging. Gratitude is framed by those who study it as both an internal affirmation of goodness as well as a recognition of external things that offer goodness and happiness.

Historically considered the ultimate public virtue in the time of Rome, an elusive emotion by philosophers, and an ecclesiastical imperative by countless theologians, discourse on gratitude within the scientific community continues to evolve rapidly. The dimensions and implications of gratitude on health and well-being, while personally meaningful for many as lived experiences, are the topics of empirical examination in the fields of psychological, health, and social sciences. Scholarship on gratitude has expanded exponentially in recent years as part of the burgeoning positive psychology movement that emerged at the turn of the twenty-first century. In the wake of the internet/technological boom that paradoxically led to both greater access to social connectivity and greater feelings of disconnect, depression, and social loneliness, the scientific community has reinterpreted gratitude to better fit an empirical framework by expanding the definition beyond a general feeling of thankfulness to an operationalized definition of deep appreciation that leads to long-lasting positive effects. Adam Smith penned one of the first publications pertaining to gratitude in his 1759 philosophical manuscript *The Theory of Moral Sentiments*. Some of the first scientific examinations of gratitude followed when sociologist Georg Simmel published *Soziologie* in 1908, and 109 years after that publication, a search on a popular scholarly web platform for titles containing the term *gratitude* now yields over 500.

Given that gratitude for so long was viewed simply as a virtue to uphold, inchoate methodological approaches to the topic, first began as simple meditations on morality. Modern

researchers have built on this foundation, taking care to note that gratitude is a complex topic to study: it defies simple classification, can be conceptualized in a multitude of ways, and when studied in the context of well-being, can often lead researchers to wonder if the two factors are merely associated or truly influenced by the other. Social science research on gratitude often takes the form of prospective observational studies and experimental cohort studies; most of the data is based on interviews or self-reported participant responses. Nationwide longitudinal surveys, cross-sectional, and retrospective cohort studies have each been utilized to study gratitude as well, leading to a robust collection of modern scientific literature on the topic. Several different cohorts, ranging from chronically ill elderly Americans to Chinese college students experiencing suicidality, have been studied in the research completed on gratitude. Though these research populations may be seemingly disparate, it is important to note that strikingly similar trends have emerged from the research. The most salient of these common themes is that the overall positive impact that gratitude has on psychological, physical, and social health and well-being.

Psychologically, gratitude has been shown to have a positive impact on one's sense of mental and emotional well-being. Across studies, scholars have shown that dispositional gratitude is related to decreased levels of anxiety, fewer frequent episodes of depression, and quicker recovery from said depression, and lower levels of loneliness. As an example of the scholarship, when Emmons and McCullough (2003) conducted a study of adults with congenital or adult-onset neuromuscular disease, they found that individuals in the daily gratitude practice experimental group experienced increased positive affect and a reduced negative affect. Benefits of the improved affect were even apparent to the participants' spouses. Though this is only one study, the scientific literature as a whole indicates that gratitude seems to positively impact a sense of direct social support, influence prosocial behavior, and fortify participants against negative emotions. Furthermore, researchers have found that gratitude itself serves as a strong protective factor against negative affectivity and behavior. Scholars have identified gratitude as a vital component of the resilience necessary to combat emotional distress incurred by financial strains, PTSD, addiction, and suicidal ideation. This research has implications for clinical interventions involving gratitude and its impact on the mental and emotional well-being of those experiencing psychological adversity.

Within the health sciences, increasing data reveal that positive psychological attributes may play a critical role in cardiac health and recovery from illness. Just as gratitude has been shown to be a positive contributor to greater psychological health, dispositional gratitude may also predict better self-reported physical health as well. In the scientific literature, examples abound of studies in which participants who were directed or prompted to practice gratitude reported benefits ranging from fewer symptoms of physical ailment to improved amount and quality of sleep to greater weekly time spent exercising. Additionally, incorporating gratitude as a component of substance abuse recovery may lead to the development of adaptive coping strategies and a greater likelihood of maintaining sobriety.

Social scientists studying gratitude focus on gratitude's impact on the wider social world. Georg Simmel, the first sociologist known to study gratitude, believed that gratitude was so imperative to social cohesion that the very fabric of society would be torn apart if gratitude were eliminated from the vocabulary of human interactions. Simmel's work goes on to assert that the equal exchange of expressing gratefulness to one another is what holds

together all of social interactions. Given this, it is ironic that empirical examinations of gratitude are scarce in the social science disciplines (with the exception being the field of psychology where an entire volume on the psychology of gratitude was recently published (see Further Reading)). The idea of an "economy of gratitude," developed by sociologist Arlie Russell Hochschild in her 1989 examination of late-twentieth-century working mothers, refers to the process of expressing gratitude as a necessary component of maintaining successful relationships. This particular framework for examining gratitude in social interactions has become a concept prolifically referenced by researchers in multiple disciplines studying emotional labor. The number of sociological studies of gratitude published after the 1980s though is sparse, and when gratitude is examined sociologically it is typically in the context of finances and economics: how gratitude works within the schema of tipping in the service industry, donating charitably, and maintaining relationships in customer marketing. Political scientists of the 1920s to now have also written sparsely on gratitude's role in political governance. When it is mentioned, gratitude is often treated as a virtue to be distrusted, one that could give way to corruption, bribery, favors, or even revenge amongst public servants. Overt displays of gratitude are frequently treated with suspicion or wariness within the system of governance.

Social structures that encourage public acknowledgment of gratitude range from the national holiday of Thanksgiving in the United States to institutional religious proclamations of thanks and praise. In fact, gratitude as a practice is extolled by each of the world's main religious traditions. Examinations of the link between gratitude and religious participation reveal that people who often attend church, frequently read the Bible, and are otherwise heavily involved in religion tend to experience more feelings of gratitude, exhibit more grateful dispositions, and self-report more motivation to express appreciation than those less dedicated to their religious practices. This trend seems to hold true across the life-span. In one particular longitudinal examination of older adults in the United States conducted by Neal Krause in 2009, more frequent church attendance seemed to strengthen the belief that God would intervene during difficult times; this in turn was found to lead to positive changes in gratitude over time. Further, gratitude seemed to be protective against the emotional duress that often accompanies chronic financial strain.

Gratitude has held the attentions of many philosophers and theologians, from Cicero to modern Christian Biblical commentators. Although gratitude was first studied exclusively in philosophical and theological contexts, other disciplines now contribute their perspectives to a dynamic discussion on the topic. Anthropologists and biologists have weighed in to discuss the historical origins and physiological implications of practicing gratitude. Economists often examine gratitude through the scope of behavioral economics, seeking to understand the ways in which a psychological posture of gratefulness may impact financial decision-making strategies. In the educational sector, researchers have commented on the positive effects of having students engage in practices of gratitude within the classroom. Even scholars of literature have examined gratitude as it is expressed in written works, from classical Greek letters to modern textbooks. Across disciplines, scholars currently studying gratitude emphasize the need for more empirical studies of the subject. The collection of empirical research on gratitude has certainly been growing, but still remains meager in comparison to the historical writings on gratitude as a purely moral, emotional subject matter. Positive psychologists, currently the most prolific purveyors of gratitude

research, lead the call for more vigorous, comprehensive studies on gratitude not only in their own field but in the realms of clinical psychology, cultural anthropology, sociology, biology, and others.

Gratitude can lead to avoiding disillusionment as well as a greater contextualization of material matters. Intentionally practicing gratitude has been shown to offer greater perspective and contribute to leading a meaningful life. Researchers Emmons and Shelton (2002) maintain that gratitude serves as a "source of human strength, and an integral element in ... the flourishing of families, communities," and individuals in multiple ways (p. 468). It may not be surprising, given the value of gratitude, that much popular discourse surrounds gratitude in American culture. From religious and cultural traditions to more modern self-help books and mindfulness exercises, as well as its noted rising popularity as a social media practice, people seem to intuitively recognize the value of gratitude. Fortunately, scholars are now intentionally measuring the psychological and social benefits of gratitude which may result in even greater numbers of people harnessing its benefits.

Personality and Volunteerism

Allen M. Omoto, Cody D. Packard, and Matthew T. Ballew

Claremont Graduate University

Prosocial action takes many forms, all of which benefit individuals (recipients and helpers), and can have broad and positive social impacts. For instance, people drive their friends to the airport, community members work together to prepare their town for an incoming storm, and parents buy cupcakes at a school bake sale to help support programming and special activities. Although prosocial, these helpful behaviors are not volunteering. Volunteering is distinguishable from other types of helping in several key ways. First, volunteerism derives from free will, and is not enacted because of obligation or social pressure. That is, the decision to volunteer is motivated by personal goals and internal traits and states. Second, volunteerism is a deliberate process by which people intentionally seek opportunities to help others who desire assistance. Third, volunteers typically do not know the recipients of their helping prior to their service. Fourth, volunteerism extends over a period of time; it is not a reflexive, one-time act like calling for emergency assistance for someone in need. Finally, in contrast to neighboring behavior or informal forms of helping, volunteerism is primarily "formal helping" in that it is usually conducted through agencies or organizations.

Social science research has identified several demographic characteristics related to volunteerism. For example, volunteering is associated with being female, being younger in age, having higher educational attainment, reporting greater religiosity, and having higher socioeconomic status. Although these characteristics may influence aspects or manifestations of a person's personality, they are different from personality traits, and thus are not described in detail here.

In general, approaches to understanding personality and volunteerism fall into one of two categories: (1) an approach that focuses on the structure of personality traits in which traits are posited to be stable over time and to broadly influence behaviors, and (2) a dynamic approach that focuses on characteristics that differ between people, can be manipulated or primed, are influenced by contextual factors, and may also change over time and experiences. These dynamic "individual difference" characteristics appear to be stronger and direct predictors of volunteerism.

Structural Approach: The Big Five

The structural approach to personality is best exemplified by research on the "Big Five" personality traits. The Big Five are purported to be fundamental and enduring trait dimensions of a person's personality, and include openness to experience, conscientiousness, extraversion, agreeableness, and neuroticism. People higher in openness tend to be more open-minded, curious, imaginative, and creative. People higher in conscientiousness are generally more self-disciplined and also more organized and achievement-oriented. People higher in extraversion are energized by being with others, and they tend to be more assertive, boisterous, and sociable. People higher in agreeableness are generally interested in maintaining relationships with others; accordingly, they tend to be more trusting, cooperative, generous, and empathic. Finally, people higher in neuroticism tend to be emotionally volatile or unstable, and are prone to unpleasant emotions (e.g. anxiety, depression, anger).

Research on the Big Five traits suggests that volunteers, compared to nonvolunteers, tend to be more open to experience, more extraverted, more agreeable, and more emotionally stable (i.e. lower neuroticism). The findings for conscientiousness are less consistent, but suggest that volunteers may actually score lower on this trait (Bekkers, 2005). Among the Big Five traits, extraversion and agreeableness seem to be the most consistent predictors of volunteerism and other helping behaviors. Because volunteerism is a form of action focused on meeting the needs of others, it is not surprising that these two traits are related to volunteerism; extraversion and agreeableness both have at their core a concern about, and interest in, other people. Extraverts are gregarious, and seek out warm relationships and exciting social activities, which can be achieved through volunteerism. People higher in agreeableness, meanwhile, tend to be altruistic, modest, sympathetic, and cooperative with others; in short, they have behavioral tendencies that well-match those of volunteers.

Interestingly, extraversion and agreeableness might also jointly influence people's volunteer behavior. In one study, college students higher in agreeableness also reported greater prosocial motivations, regardless of their degree of extraversion. However, among students lower in agreeableness, extraversion was positively related to prosocial motivation (Carlo, Okun, Knight, & de Guzmán, 2005). In other words, extraversion may be especially important in predicting volunteerism among people lower in agreeableness. Additional findings from this study suggest that the predictive power of these Big Five traits may depend on an intervening and more proximal construct, namely prosocial motivation. Exploring specific motivations related to volunteerism is consistent with a dynamic approach to personality, and is described below.

Dynamic Approach: Traits and States

Not all aspects of a person's personality are stable; in fact, many of the strongest and most direct predictors of volunteering are characteristics that vary between people and within a person over time. Furthermore, many of these dynamic characteristics can be heightened or dampened via intentional or contextual influences (e.g. manipulations, priming). Research suggests four major types of dynamic personality characteristics that reliably predict volunteerism: (1) general prosocial orientation, (2) volunteer identity and community connections, (3) empathy and perspective taking, and (4) personal motivations and goals.

Separate from research on Big Five traits, there have been several attempts to define and measure general helpfulness, concern for other people, and prosocial propensities. These measures of altruistic or prosocial orientations tap predispositions toward caring about other people and taking action on their behalf. It is not surprising, therefore, that people who score higher in prosocial orientation or altruistic personality also are more likely to engage in volunteerism-related activities. In fact, reports of volunteer behavior have sometimes been used to validate measures of prosocial orientation under the logic that for a measure of prosocial orientation to be valid, it must consistently predict prototypic prosocial actions like volunteerism.

A second set of dynamic characteristics frequently related to volunteerism include identities and community connections. When people identify themselves as volunteers and consider volunteer work as a defining characteristic of who they are, they can be said to have a volunteer role identity or to be higher in volunteer identification. People with stronger volunteer-related identities are more likely to persist in volunteer tasks and to stay active as volunteers. Similarly, research suggests that when people feel connected to a community of other people who care about a cause or group of people (i.e. they have a greater sense of community), they are more likely to take action, including volunteering, on behalf of that cause or group.

Identity and community are both related to volunteering, but they are also related to each other. Oftentimes, being part of a community also means that a person identifies more with that group or volunteer role. In other words, these predictors of volunteerism are reciprocally related to volunteering and each other. For example, one longitudinal study of AIDS volunteers conducted over a six-month period demonstrated that volunteers who felt connected to the community of people affected by HIV and AIDS volunteered more at an AIDS service organization. As suggested by data collected later on, these same people developed stronger connections to, and integration into, that community (Omoto & Snyder, 2002). Thus, feeling connected to others, like identifying with a group or one's volunteer role, is not only a predictor of volunteerism, but also a consequence of volunteerism.

A third category of dynamic personality predictors of volunteerism includes empathy and perspective taking. Empathy refers to the tendency to feel another person's feelings and to experience compassion and sympathy for others, especially other people who are suffering. Perspective taking is sometimes considered one aspect of empathy, but also can be considered on its own. It refers to an ability to effectively put oneself in another person's shoes and to see the world from their vantage point or perspective.

Research suggests that both empathy and perspective taking are related to volunteering and other helping behaviors. To the extent that people experience greater empathy or more readily take the perspective of others, they appear more likely to volunteer, as well as to sustain volunteerism for longer periods of time. Moreover, both empathy and perspective taking have been conceptualized as relatively enduring traits, as well as temporary psychological states that can be induced or enhanced through specific instruction or contextual cues. For example, in one experiment, college students were directed to imagine the feelings and emotions of a person who was videotaped thinking aloud (perspective taking condition) or to consider the production quality of the video (control condition). Participants in the perspective taking condition were more willing to volunteer to help incoming students than participants in the control condition. Furthermore, because this study relied on an experimental manipulation of perspective taking, it also suggests that perspective taking may actually cause empathy and volunteerism (Oswald, 1996).

A good deal of research on volunteerism has explored individual-level motivations and goals that people pursue through volunteering. That is, from this perspective, people engage in volunteer work to satisfy personal goals or agendas for action. Research suggests that people may have relatively self-focused motivations for volunteering, like improving job-relevant skills or prospects, deepening understanding of a current societal problem, building social networks, or even to feel better about themselves. Motivations also can be predominantly other-focused; in fact, other-focused motivations tend to be consistent and strong predictors of volunteering. Thus, people may be moved to volunteer because of personal values that compel them to help and "give back," or as one way to assist groups of people and communities to which they are committed. Regardless of specific motivation type (e.g. self-, other-focused), research suggests that volunteers report greater satisfaction, enjoyment, and intentions to persist when their volunteer work allows them to directly address a specific and personal motivation.

An important point in work that focuses on motivations for volunteering is that the motivations of individuals, even when volunteering for the same cause, may differ. In addition, any person's main motivation for volunteering may change over time and experiences. For example, the findings of one meta-analysis of age and motivations for volunteerism suggests that motivations for volunteering may shift with age: younger people tend to report greater self-related motivations (i.e. to improve their career; to gain greater understanding of themselves or an issue), whereas older people tend to report greater social reasons (e.g. to stay connected to others; to meet new people; Okun & Schultz, 2003).

Related to age-based differences in motivation, theories of psychosocial development suggest systematic and predictable changes in volunteer motivation over the life course. For example, generativity, or the desire to leave a lasting legacy for future generations, increases later in life (when people are in their 40s to 60s) and is related to a range of behaviors, including volunteerism. In fact, cross-sectional research suggests that generative motivation is reliably related to volunteerism at all ages, but also better predicts the volunteerism of middle-aged and older adults than volunteering by younger adults.

Morning vs. Night People

Matthew A. Pardo and Joseph R. Ferrari

DePaul University

The morningness chronotype (as represented by the lark) refers to an early sleeping and waking pattern. Individuals with a preference for morningness are known for achieving peak mental and physical performance at earlier times of the day (Adan et al., 2012). In contrast, individuals with a preference with the eveningness chronotype (as represented by the owl) exhibit a late sleep and wake pattern and are known for their performance towards evening-type behaviors. According to Tonetti, Fabbri, and Natale (2008), around 60–70%, of the population falls within the middle of these two extremes. While the focus may be represented by the extremes, the majority of the population may exhibit preferences towards morningness or eveningness.

Human chronotypes are related to an endogenous biological clock (internal clock) which regulates daily functions such as gene expression and sleep performance (Roenneberg, Wirz-Justice, and Merrow, 2003). Research from Wittmann, Dinich, Merrow, & Roenneberg (2006) explains that this internal clock contains a period of roughly 24 hours, which is also known as a circadian cycle. This internal clock is located in the *suprachiasmatic nucleus*, is a group of brain cells that are located in the hypothalamus (Moore, Speh, & Leak, 2002). The suprachiasmatic nucleus actively processes various information in order to develop circadian rhythms, or a routine schedule for our behaviors (Moore, et al., 2002). Within this schedule, there are certain hormones (mainly cortisol and melatonin) that are secreted at specific times, as well as the peaking of our body's temperature (Randler & Schaal, 2010). These rhythms contribute toward an individual's chronotype and lifestyle.

Cortisol, commonly known as the stress hormone, is released from the adrenal gland and has potential links in the awakening response. It has been recorded that there is a significant difference in cortisol levels in morning-types in comparison to evening-types after waking (Griefahn & Robens, 2008; Bailey & Heitkemper, 2001). In early risers, cortisol peaks during the morning, while late risers seem to have a delayed or later peak of cortisol (Kramer et al., 1999). Using salivary cortisol serum samples, morning-types had an increase in cortisol release 55 minutes earlier when compared to evening-types (Bailey & Heitkemper, 2001). In contrast, melatonin is released during the late evening or at night, and is believed

that be the best predictor for sleep onset in organisms (Benloucif et al., 2005). It has been documented that morning-types experience the release of melatonin three hours earlier than evening-types (Mongrain et al., 2004; Griefahn et al., 2002). Therefore, it is possible that an earlier release of melatonin may coincide with falling asleep earlier.

In addition to the secretion of cortisol and melatonin, there seems to be a noticeable difference in the peaking of body core temperature between the two chronotypes. According to Chelminski, Ferraro, Petros, and Plaud (1999), the morningness chronotype is associated with a rapid increase in body temperature in the morning, and a decrease in temperature throughout the rest of the day. In contrast, evening-types tend to have peaks in their body temperature during the middle of the day, and in some cases, at night (Chelminski, et al., 1999). It has been observed that morning-types have an earlier circadian temperature phase (approximately two hours earlier) than evening-types (Duffy et al., 1999; Gupta & Pati, 1994). Because there are observed differences in times for the peaking of body temperature, this difference may be an additional factor as to why morning-types tend to wake/sleep at earlier times, and are more suited for daytime activities when compared to behaviors of the evening-types.

While there have been observable internal differences between the two chronotypes, there still may be underlining factors that explain these differences. It has been hypothesized that between external factors (*Zeitgebers)* and the suprachiasmatic nucleus, are present in the natural environment. The most common example seen in the light/dark cycle (Adan et al., 2012). Based on societal norms, humans are normally active during the daylight hours, while resting during late evenings. With that being said, not everyone possesses this morningness chronotypes. The light/dark cycle provide cues for activity levels. Internal individual differences are a product of one's external factors which may influence habitual behavior, which in turn modifies our internal clocks (Adan et al., 2012).

Because humans are constantly adapting to their environment, specific chronotypes are not consistent throughout one's lifespan; there seems to be an age-specific shift towards morningness and eveningness. Using a sample size of 8,972 participants, aged from 10–87 years old, Tonetti et al. (2008) administered a cross-sectional survey in Italy. Results from this study showed that in adolescence, there is a pronounced shift toward eveningness. During this stage, adolescents and early adults tend to go to sleep and wake up later than other age groups. Additionally, as the aging process occurs, there is a gradual shift toward the morningness chronotype; this early waking and sleeping preference is even more pronounced in those over the age of 50 (Tonetti et al., 2008). This shift back into the morningness chronotype could potentially be associated with the expected normal hours of operations in the workforce, since "normal" working hours follow the 8 a.m. to 5 p.m. timeline.

When relating the findings of Tonetti et al. (2008) to how our society functions as a whole, it is important to understand that preference toward functioning during the hours of daylight exist. This would potentially cause an advantage to those who possess the morningness chronotype in comparison to those who exhibit nighttime behaviors. Evening-types have to shift their preferred sleeping times in order to adjust to their working or school activities. Ultimately, this causes a negative interference with their preferred sleeping habits (Wittmann et al., 2006). This phenomenon, known as *social jetlag*, describes routines

(e.g. work, school, and so on) as a leading factor in sleep deprivation. This disturbance in sleeping habits is comparative to jetlag because individuals experience a disturbance in their circadian clocks, or natural patterns. Therefore, evening-types tend to experience higher levels of social jetlag and increased sleep deprivation, when compared to morning-type individuals (Wittmann et al., 2006). This effect normally leaves evening-type individuals trying to compensate on days off for their lack of sleep during typical work days (Wittmann et al., 2006). Though social jetlag is mainly seen in evening-type individuals, morning-type individuals may also experience disturbances in their sleeping patterns. If on their free days, an individual stays up later than usual, and wakes up at their normal circadian wake up time, they would also experience a disturbance in their circadian clock (Wittmann et al., 2006).

Several studies have shown a relationship between chronotype well-being and performance; with the primary focus on evening-types. It has been observed that there are higher levels of psychological distress (primarily depression) among those in with the eveningness chronotype; with the highest prevalence of depression seen in adolescents and young adults (Chelminski et al. 2009). It has also been observed that evening-types are more prone to insufficient levels of sleep. These observed higher levels of depression may be explained by social jetlag; it is plausible that social demands, such as school and work, are disrupting their preferred sleep/wake cycle. Failure to adjust to these social demands may significantly affect one's achievements and performances; it is concluded that evening-type students perform worse in school when compared to those who possess the morningness chronotype (Wittmann et al., 2006). While there are positive correlations between sleep deprivation and depression (which consequentially negatively influences individual performance), there may be other underlining factors such as drug use.

While drug use is not chronotype specific, it seems that evening-types have a higher probability of experiencing disruptions in their sleep/wake cycles (Prat and Adan, 2011). Therefore, it is possible a higher probability of drug consumption (both legal and illegal) with individuals who experience the consequences of social jetlag. While social jetlag is most prevalent in the adolescent and young adult age group, drug consumption is not age specific. It is suggested that stimulants (caffeine and nicotine) are consumed in order to better adjust to be more active during the mornings, whereas depressants (alcohol, and cannabis) are used in the evenings to promote sleep (Adan et al., 2012). While this may help individuals adjust to their social environment, there is also evidence that the effects of drug use may persist for weeks or even months causing disturbances in the circadian rhythm (Adan et al., 2012).

In the human population, the majority are not affiliated with either extreme chronotype; but a preference in morningness or eveningness behaviors is expressed or exhibited. Individual differences play a key component in how an individual is able to perform during the day and night. Because of these individual differences, some people are better suited to perform during the day, while others are better suited to perform at in the late evenings/night. It is evident that society caters toward daytime behaviors; therefore, those who are more active during the day, or have adjusted toward morningness, will have an advantage when compared to those who struggle to adapt. Advances in technology, as well as differing times of shift work (evening and night shift), may allow evening-type individuals to be

more productive in their preferred hours. While there seems to be many risk factors and health implications in evening-type behaviors, maintaining a "norma," healthy sleeping schedule may prevent these risk factors from occurring. Therefore, regardless of an individual's chronotype, it is necessary to understand one's biological preference toward the morningness/eveningness spectrum and function accordingly. Understanding how one's body responds to external cues may contribute to increased productivity, but more importantly, one's well-being.

Diversity in Work Teams

Sara Langford

California State Polytechnic University

Diversity is variety. In terms of organizations, "diversity" is used to describe variety in human characteristics (e.g. physical location, culture, race, ethnicity, sex, age, religion, ability, personality, intelligence, personal experience, etc.). These characteristics can be categorized as relations-oriented or task-oriented (meaning they are likely to impact either relationships or tasks). Having a membership with variety (diversity) on these characteristics impacts teams in most modern organizations. Further, because diversity is a broad concept, it has a broad impact as well; it influences group cohesion, functionality, and other process-related variables, as well as creativity and task performance.

Relevance of Diversity to Teams

With organizations globalizing and using technology to cross geographic boundaries that were once a hindrance, diversity has become a reality, a challenge, and a boon in the workforce. Geographically dispersed work groups are now commonplace. However, diversity does not only occur at a distance; ever-growing minority groups in the (US) population means this is an issue even within domestic organizations that are centrally located. Work groups can have a wide variety of nationalities represented even in places that were at one time quite homogenous. In addition, a number of laws that have been enacted since the 1960s (e.g. Title VII of the Civil Rights Act, the Americans with Disabilities Act, the Age Discrimination in Employment Act, etc.) creates a more favorable environment for increasing diversity at work. These laws create more diversity in terms of a number of demographic variables, including race, ethnicity, sex, age, religion, and disability. Of course, diversity can also come in nondemographic forms as well. Individual differences on intelligence, personality, and personal experiences also can contribute to unique work environments for teams. The courts provide a context that is familiar to most Americans and an example where team diversity is already heavily considered. Lawyers put much thought into how the heterogeneity or homogeneity of a jury could impact trial outcomes.

Anyone who has served on jury duty can understand the forethought lawyers put into this as evidenced by the thorough questions asked during jury selection.

While diversity is an important consideration for organizations on the whole, it is an especially relevant issue for work teams in particular. This is because individuals in work teams interact. That is, diversity in individual differences is more likely to have an impact if those individuals interact than if they work in separate parts of an organization and do not interact. For example, if employees of different religions both work for the same organization, but do not interact, it is unlikely that their religious differences would affect them much. On the other hand, if they work together in a team, these same differences could impede or improve their success.

Work teams can take many forms; they can be small, large, centrally located, geographically diverse, highly interdependent, more independent, etc. Broadly defined, work teams are groups of three or more, but fewer than 50 employees whose work requires their cooperation. Some of these team characteristics (location, level of interdependence, size, etc.) can impact which types of diversity matter and to what extent they matter. For example, a team with religious diversity might not be impacted by that variable if they also have geographical diversity that requires them to communicate solely through email. In contrast, if the team has religious diversity, but are located together and interact in person, religion might impact their team outcomes.

Theories Relevant to Team Diversity

Among many theories that are relevant to the understanding of diversity in teams, two stand out. Attraction-selection-attrition theory describes how individuals tend to be attracted to groups of people (teams) that are similar to themselves. These groups also tend to select individuals who are similar to the group. Finally, individuals who enter the group, but are dissimilar, tend to leave when this becomes salient. In combination, this model explains how groups become homogenous. In addition, social identity theory provides many insights in terms of ingroup/outgroup dynamics. When part of a group, individuals base some of their own personal identity on that group membership. They also pay more attention to things that differentiate their group from others. This theory can help in the understanding of how diversity can be an obstacle (people from diverse backgrounds see each other as outsiders), but also how to improve cohesion in a diverse group (by making salient the commonalities among those in the group).

Impact on Cohesion, Creativity, and Task Performance

In general, diversity can be problematic for work teams in terms of group processes. Particularly, group cohesion suffers when a group is very heterogeneous. These groups often have decreased commitment, increased turnover, and group members communicate less with one another. Groups like these have been shown to have increased conflict. However, a meta-analysis by Horwitz and Horwitz (2007), raised questions about this conclusion with their finding that there was no relationship between diversity and social integration.

Creativity, on the other hand, seems to benefit from diversity in work teams. Creativity is particularly important for organizations, providing an edge in the competition for

resources and business. Groups that have diversity have a wider swath of knowledge and experiences to tap into and, as a result, tend to be more innovative than homogeneous groups.

The relationship between diversity and task performance is less clear. Some research has shown that diversity increases performance, while other studies show it is detrimental. Yet others find no relationship at all. A meta-analysis by Horwitz and Horwitz (2007) indicated that task-related diversity (e.g. organizational tenure, process knowledge, etc.) was positively related to performance, but bio-demographic (relations) diversity was unrelated.

While it seems that group processes suffer and creativity benefits from diversity, a clear conclusion cannot be made for any of these relationships as the research is still quite mixed. It helps to consider, then, the different effects of various types of diversity. In addition, there are a number of probable moderators to consider.

Impact of Diversity by Type

The types of diversities that groups experience can be separated into relations-oriented diversity and task-oriented diversity. Relations-oriented diversities are those that are most directly related to intra-group relationships (e.g. ethnicity, age, sex, etc.), while task-oriented diversities are variables that are likely to impact performance (education, organizational tenure, functional background, etc.).

A review of the literature indicates that relations-oriented diversity can impede group processes, but is less consequential in terms of performance. A closer look at some of these specific types of diversities can shed more light. Ethnicity, gender, and age are commonly studied in the context of work teams. The research on ethnicity indicates that it might be an impediment to communication. Groups that are ethnically diverse see fewer friendships formed among group members and an increase in emotional conflict. The relationship of ethnicity with performance is more mixed, though, with ethnic diversity sometimes improving and sometimes impeding this outcome. Gender diversity similarly relates to a decrease in communication, but research on performance is mixed. Age diversity has the same pattern of relationships. Overall, it seems that these variables are an impediment to group processes, but can sometimes be beneficial for performance.

Task-oriented diversity appears to be beneficial for performance but slightly detrimental for social integration. Tenure, education, and functional specialization are commonly studied variables in the context of work teams. Tenure diversity improves performance, but can also result in more emotional conflict and higher turnover. Education diversity and diversity in job experience similarly result in better team performance, but also higher turnover rates. Diversity in functional specialization (subject-matter knowledge) increases task conflict, but also improves creativity and performance in general (e.g. increased effectiveness and efficiency). Overall, it appears that task-related diversity can sometimes create conflict and increase turnover, but is beneficial for performance.

Moderators of Diversity's Impact on Teams

Because there are mixed results in the research on diversity in work teams, it is helpful to consider some of the moderators of this relationship. One of the clearest findings is that an environment that is supportive of diversity results in better outcomes for diverse groups.

In a supportive climate, diversity can result in a stronger sense of interactional justice, less aggression, and even better financial performance. Further, cultures that are more egalitarian and collectivist allow diversity to have more desirable outcomes.

In addition to the external environment, the mentality of those in the group is a very important moderator as well. If team members have a high learning approach orientation (a desire to advance their skills or abilities), diverse teams will perform better. Similarly, if team members have shared mental models about diversity, outcomes improve. If the diverse team has a strong team orientation, they experience less conflict.

Other situational variables that moderate this relationship are characteristics of the task itself. For example, how much interdependence is required by the task can impact the outcomes of diversity. Diverse teams that are more interdependent find it easier to attain positive outcomes than diverse teams that are less interdependent. The salience of the particular type of diversity to the task at hand is also very important. If a task is very gender-related, it is more likely that gender diversity will relate to important outcomes. Finally, how routine or novel a task is can lessen or increase the impact of diversity on outcomes. Diverse teams that are completing routine tasks are less likely to experience conflict than diverse teams doing novel tasks.

Time is yet another variable that moderates the impact of diversity on important team outcomes. Team longevity is related to less conflict in diverse teams. Further, if diversity is having a negative impact on group cohesion, that effect lessens over time, alleviating some of the concern over group processes. This moderator should be considered more seriously, though, because many diverse teams are "cross-functional" teams and exist short-term for specific projects.

Because diversity benefits performance and is a reality for most, if not all, organizations, it is common for organizational leaders to try to create an environment that optimizes outcomes and minimizes problems for diverse teams. One way to do this is by implementing diversity training. In instances when people have attitudes about diversity that are not positive, diversity training can help. Teaching team members about diversity increases their self-efficacy, which, in turn, allows them to work more effectively together. However, this only works if there is diversity in the team. If the team is not diverse, training them on the topic can actually worsen attitudes toward diversity. If the team is diverse, though, diversity training and, in particular, conflict management, can help increase their viability.

The leadership style implemented in diverse work teams can also affect team outcomes. In particular, transformational leadership is an effective style for diverse teams, improving outcomes for both teams that have relations-related and task-related diversity. Transformational leaders inspire dedication among followers; perhaps that dedication aids cohesion in diverse groups.

Future Research on Diversity in Teams

Because there are so many types of diversity, it is problematic that most studies in the current body of research only report one or two types; it would be beneficial for researchers to report on many types of diversity to give a more accurate picture of the teams they are studying. A team can be diverse on some aspects and nondiverse on others. Perhaps teams

that are diverse in multiple areas have a more difficult time achieving positive outcomes than those who have only one area of diversity. Also, certain types of diversities, when combined, might have a synergistic impact. Reporting on many types of diversity would allow for more meta-analyses on diversity in work teams and would address these interactions that have not yet been explored. Knowing about these interactions could help organizations support and sustain teams long enough that they still benefit from improved performance, but have had time to move beyond and grow from initial problems with group processes.

Creativity in the Workplace

Yeun Joon Kim[1], Geordie McRuer[2], and Jacob B. Hirsh[3]

[1] *University of Cambridge*
[2] *Bastet Strategy*
[3] *University of Toronto*

Creativity is commonly defined as the generation of ideas, products, or behaviors that are novel and useful. Organizations that are able to harness the creativity of their employees tend to be more profitable and successful than their less creative counterparts. Below, we review the key individual and contextual factors that relate to creativity in the workplace.

Individual Differences

Openness/Intellect

Openness/Intellect is one of the five major dimensions of personality, and is the trait that is most consistently associated with heightened creativity and innovation at work (Hammond, Neff, Farr, Schwall, & Zhao, 2011). People who score highly on this trait excel at creative tasks for multiple reasons: (1) Increased cognitive flexibility allows for more divergent thinking styles; (2) a larger working memory capacity increases the chance of combining distal ideas; (3) higher levels of implicit learning facilitates the unconscious generation of novel associations; and (4) a stronger motivation to explore new ideas leads to greater engagement with the creative process (DeYoung, 2014).

Intrinsic Motivation

Intrinsic motivation reflects the inherent desire to perform an activity, regardless of external rewards. Higher levels of intrinsic motivation for a given task are strongly associated with increased employee creativity (Amabile, Conti, Coon, Lazenby, & Herron, 1996). Intrinsic enjoyment of a task may sometimes, however, result in a greater focus on the novelty of a creative product, with less consideration for its usefulness. This tendency can be overcome when intrinsically motivated people also have a strong desire to help others,

resulting in an increased focus on the usefulness of their creative products and ideas (Grant & Berry, 2011).

It has also been proposed that strong external incentives can decrease creativity by undermining intrinsic motivation. Others, however, have suggested that such incentives can provide positive reinforcement for a person's creative abilities. A recent meta-analysis in this area suggests that extrinsic rewards are slightly better at predicting the quantity of work output, while intrinsic motivation is much better at predicting the quality of creative work (Cerasoli, Nicklin, & Ford, 2014).

Creative Self-Efficacy

Creative self-efficacy reflects the extent to which an individual believes that he or she is capable of being creative. Higher levels of creative self-efficacy, which can fluctuate in response to successes and failures, are associated with increased engagement and improved performance during creative tasks (Tierney and Farmer, 2002). Creative self-efficacy can be fostered through the adoption of a learning goal orientation, in which a person focuses on long-term mastery of a task, rather than focusing only on short-term performance (Gong, Huang, and Farh, 2009).

Multicultural Experience

Researchers have also found that time spent living abroad is associated with higher scores on tests of creativity. Adapting to new cultural environments demands novel patterns of thought and behavior, which stimulates creative thinking. Multicultural experiences among executives has similarly been related to firm-level creative innovation. In a longitudinal study of fashion houses over 11 years, those firms whose executives had the greatest depth of multicultural experience also displayed the highest levels of creative innovation (Godart, Maddux, Shipilov, & Galinsky, 2015).

Contextual Characteristics

Leadership

Employee creativity is more likely to emerge with supportive leadership practices, including fair performance assessments, open interactions between supervisors and subordinates, and enhanced support for work teams (Shalley, Zhou, & Oldham, 2004). Compared with directive or autocratic styles, empowering leadership, in which leaders share their authority and encourage employees to take on more responsibility, has also been found to increase followers' creativity (Zhang & Bartol, 2010). Transformational leadership likewise helps increase creativity because it boosts employees' intrinsic motivation to perform well at their jobs. Higher quality relationships between leaders and employees can also foster a climate that is supportive of innovative practices (Scott & Bruce, 1994), stimulating creative performance above and beyond the effects of individual employee attributes (Shalley & Gilson, 2004).

Social Environment

Having support from one's colleagues can also be important for fostering creativity at work. Amabile et al. (1996) found that creativity is associated with encouragement from one's work group, including constructive feedback, shared commitment to the project, and a collective openness to ideas. Social support from colleagues, supervisors, family, and friends, are all known to increase positive mood states among employees, leading to higher levels of creativity. In contrast, harsh criticism of new ideas and a lack of support tends to inhibit creative production and encourage more conventional thought and behavior (Shalley, Zhou, & Oldham, 2004).

Job Complexity

Job complexity refers to the amount of autonomy, feedback, significance, identity, and variety that employees experience while performing their jobs. More complex jobs tend to elicit greater interest and engagement from employees, which in turn is associated with higher levels of creativity (Shalley et al., 2004). Routinized jobs with minimal complexity, on the other hand, are the least likely to encourage creative behavior.

Organizational and National Cultures

An organization's cultural can have a strong impact on the creativity of individual employees. For example, Scott and Bruce (1994) demonstrated that employee creativity is more likely to thrive within an organizational climate that supports innovation. Yuan and Woodman (2010) found that innovation-supportive climates increase creative performance by reducing the perceived risks associated with creative behavior, and increasing expectations for positive outcomes. Amabile et al. (1996) likewise found a positive effect of organizational cultures that encourage creativity by valuing risk taking behaviors, providing fair and supportive evaluation of novel ideas, and encouraging employee participation in decision making processes.

   The broader culture environment in which an organization is situated can also influence its creativity levels. Cultures that demand a rigid adherence to existing social norms can inhibit the creative generation of novel practices. For example, US states with tighter social norms also tend to generate a smaller number of patents per capita, a common measure of creativity and innovation (Harrington & Gelfand, 2014). Organizations that adopt rigid social norms similarly tend to be less receptive to creative ideas and generate fewer creative products.

Knowledge Creation in Organizations

Much of the creativity that occurs in the workplace is enacted as the creation of new knowledge, which depends on a continuous dialogue between the tacit and explicit knowledge held by employees (Nonaka, 1994). Tacit knowledge is that which is implicitly understood but hard to codify and communicate to others, while explicit knowledge is

easily codified and transferred to other members of an organization. According to Nonaka's (1994) dynamic theory of knowledge creation in organizations, these forms of knowledge are combined through four processes: socialization (integration of tacit knowledge), externalization (conversion of tacit knowledge into explicit knowledge), combination (integration of explicit knowledge), and internalization (conversion of explicit knowledge into tacit knowledge). The creation of new knowledge is argued to involve a repeated application of these processes.

Given the importance of knowledge integration for creativity, the management of organizational knowledge is an important topic of study. Creativity tends to increase when knowledge is openly shared among team members and by managers. Possessing a larger pool of domain-relevant information within a group of employees is similarly associated with higher levels of workplace creativity. Lastly, higher levels of creativity are most likely to emerge from employees who actively increase their own pool of knowledge by seeking out new information from others (Nonaka, 1994).

Individual Differences in Creativity

Mark A. Runco

Southern Oregon University

Individual Differences in Creativity

Individual differences in creativity have been of great interest for decades. The field of creativity research is itself not all that old, but the interest in individual differences goes back all the way to the beginning. The same is true of the *nomothetic* approach, with its emphasis on groups, general tendencies, and universals, as is indicated by the theories and research that look for characteristics, capacities, or tendencies shared by all creative individuals, or at least by groups of creative people. Indeed, general tendencies need to be taken into account, even when the interest is in individual differences. There are domain differences, for example, with creative artists manifestly different from creative scientists and creative leaders, just to name one example where you would expect to see individual differences (e.g. persons varying along a continuum) that are only meaningful when group variations are also recognized. This is true of domain differences, but there are also predictable variations in different age groups and even in different historical eras.

That being said, the *idiographic* view, with its emphasis on individual differences, receives an enormous amount of attention, probably because of the nature of creativity. Self-expression can be quite creative, for example, and it is by definition idiosyncratic. Indeed, many of the characteristics of creativity require individuality (e.g. autonomy, intrinsic motivation, rebellion, contrarianism, divergence), and these imply that individual differences must be recognized. The present entry reviews the research and theories of individual differences in creativity. Universals are brought into the discussion here and there, to ensure a comprehensive view.

Creativity does not depend on any one capacity. It is instead a complex or *syndrome* (MacKinnon, 1965; Mumford & Gustafson, 1988). Whatever the label, the key idea is that creativity is the result of cognitive, emotional, attitudinal, motivational, and psychic processes. The present chapter touches on individual differences in each of these categories, though of course the realistic view is that creativity depends on an interactions among them.

Some theories also include a social component in the complex, the idea being that social recognition is required, but the parsimonious approach holds the social components as useful for fame and impact rather than creativity per se. Indeed, both fame and impact can and should be extricated from the creativity complex (Runco, 1995). This can get complicated when the focus is on creative achievement, for it does require social recognition. But the key parts of creativity – bringing something original and effective into being – need not be socially recognized, and various expressions of creativity (i.e. everyday creativity, personal creativity, and the creativity of children) do not depend on any social tendency. Indeed, because originality is required for all creativity (Runco & Jaeger, 2012), if anything, there is an asocial or even antisocial requirement for creativity! Only by being able to ignore expectations and other social pressures can the creator produce something that is original, novel, rare, or unique. The capacity to ignore social pressures is well explained by the personality theories that point to the unconventional tendencies, autonomy, and contrarianism as part of the creative personality.

This brings us to the topic of individual differences in personality, which is for several reasons the best starting point. Most of the early investigations of creativity focused on the personality traits that were thought to underlie all creativity, so by starting with personality we can see how the field of creativity studies evolved.

Individual Differences in Creative Personality

A number of seminal studies on creativity came out of the Institute for Personality Assessment and Research in the 1950s, 1960s, and 1970s. Often, traditional personality measures were used, including the MMPI, the California Psychological Inventory, the Adjective Check list, and the Thematic Apperception Test. There was fair agreement among the measures and indeed a short list of core characteristics was identified (Barron, 1995; Barron & Harrington, 1981). These include flexibility, openness to experience, independence, wide interests, intrinsic motivation, risk tolerance, autonomy, playfulness, unconventionality, curiosity, and humor. The work at IPAR took those domain differences that were mentioned above into account, and samples represented distinct fields (e.g. writers). Several interesting investigations sampled architects, the idea being that they represented a blend of skills and drew from aesthetics but also engineering. Another attraction of the work at IPAR was the comparison of different levels of creative achievement. World-class creators were often compared with less accomplished groups (see Dudek & Hall, 1991, for a follow-up study of architects). This idea of looking to high-level creators caught on, probably because any uncertainty of whether something is in fact creative is circumvented if the creativity is unambiguous and beyond question.

Gardner (1980) used this reasoning when he developed his well-known theory of multiple intelligences–which really represents another way of acknowledging the domain differences mentioned several times already in this chapter. Gardner's work pointed to musical, mathematical, verbal-symbolic, bodily-kinesthetic, spatial, interpersonal, intrapersonal, and naturalistic domains. Gardner's sampling of unambiguous cases included his case studies of Freud, Stravinsky, Einstein, Picasso, Gandhi, T. S. Eliot, Martha Graham. He concluded that there were two things that were shared by all creators.

They are child-like and self-promoters. This conclusion may be a reflection of his focus on high-level creators. Self-promotion may not be vital for creators unless they are working towards broad social recognition.

Individual Differences in Creative Cognition

Research on the cognitive bases of individual differences was not far behind the personality research on creativity. Guilford (1968), for example, developed several measures of divergent thinking, many of which are still used today (see also Runco, 1991; Torrance, 1995). The longevity of Guilford's work probably reflects the fact that he developed a broad theory, as well as measures well-tied to the that theory. The logic of divergent thinking is also compelling. His "structure of intellect theory" was criticized but one part held up: Certain cognitive processes allow individuals to produce new ideas. This is the most likely when the cognitive processes direct thinking in different directions, hence the label, *divergent* thinking. Logically, if an individual is thinking divergently, it is likely that he or she will find original ideas. This ties divergent thinking to creativity because originality is a requirement of creativity. It is necessary though not by itself sufficient (Runco & Jaeger, 2012). Divergent thinking is distinct from convergent thinking where the cognitive processes converge on one correct or conventional answer. Again using logic, it is unlikely that convergent thinking will lead to original ideas. Convergent thinking is useful in school, or on an IQ test, or when the problem at hand is well defined.

Individual differences are readily apparent when people think divergently. In fact, they are obvious in various ways, including ideational fluency, which is defined as the number of ideas produced. In one of my own early investigations of divergent thinking I administered a divergent thinking task that asked students to "list as many things as they could that moved on wheels." They were given as much time as they wanted, which is an important consideration, given that the most original ideas are found only after obvious ideas are depleted (Mednick, 1962). Indeed, individual differences in divergent thinking will not be found unless examinees are given quite a bit of time – and in fact they should not be informed that they are being timed! Reliable divergent thinking scores are found when the tests are given under *game-like* rather than *test-like* conditions. If divergent thinking tests are given under test-like conditions, the only examinees who will earn high scores are the ones who do well in school and are good at taking tests. Creative examinees, on the other hand, will be found when the testing conditions are game-like. The aforementioned individual differences in ideational fluency were quite obvious in that I found a mean of 17 (across 240 middle school children), but one boy gave 120 ideas, and of course, with a mean of 17, quite a few students were giving fewer than 10 ideas. There was a wide range, or obvious individual differences, in fluency.

There are comparable individual differences in *ideational originality* and *ideational flexibility*. The first of these can be objectively scored, which is a huge advantage for divergent thinking testing, by identifying uncommon ideas. The most uncommon idea is unique; only one person gives it. Only one student in the sample mentioned above (the boy who gave 120 ideas) produced the response, "curricle." Other ideas were uncommon, though not entirely unique. They too are indicative of originality, even if they may be given by 1%,

3%, or even 5% of the sample of examinees. Ideational flexibility, on the other hand, represents the number of distinct conceptual categories are used by an examinee. If the individual gives "car, automobile, Ford, truck, pick-up, 18-wheeler, and motorcycle," for example, only one or two categories are used, in contrast to someone who says "car, luggage, skateboard, jets, trains, and my mom when she is driving." There are clear individual differences in both originality and flexibility, just as there are for fluency. It can be useful to take all three dimensions into account in a sort of profile, and various new indices of divergent thinking have been proposed now that computers have been employed for creativity assessment. Divergent thinking tests have more than reasonable predictive validity, even in 50-year longitudinal research.

Creative Style

Another approach to understanding individual differences uses *creative style*. The word style is used here as it is in the work on cognitive style (e.g. impulsivity vs deliberation). Style is distinct from ability in that the latter measures "how much" (e.g. "how much intelligence – what is the level of intelligence?") and the former focuses on "how" (e.g. "how does the individual process information?"). Research on abilities often relies on one or very few dimensions, and each person in a sample is placed somewhere on a continuum. The styles approach is different in that its primary objective is to determine which methods different people use when solving problems. Different continua are therefore used.

Geir Kaufmann and Oyvind Martinsen, for example, developed a measure of *assimilator style* or an *explorer style*. Martinsen wrote (in the 1995 Creativity Research Journal):

> A-E theory posits that there are individual differences in the dispositions toward relying on past experience and seeking novelty in cognitive activities. These individual differences manifest themselves in relatively stable, cognitive, strategic dispositions where assimilators give priority to upholding cognitive economy and explorers seek new types of solutions and new ways of solving problems. Thus, explorers are seen as more innovative and original and are posited to perform better than assimilators when there is a high level of novelty (low degree of relevant experience) in the task. In contrast, assimilators are posited to perform better when they have a high level of relevant experience.
>
> *(p. 292)*

Not surprisingly, Martinsen was interested in the interaction between style and the use of experience. His empirical research confirmed that assimilators did indeed benefit more from experience than did the explorers, at least on insight problems.

Other styles have also been related to creativity. Min Basadur, for example, identified individual differences using a measure which categorized managers as generators, optimizers, conceptualizers, or implementors. Field experiments suggested that the optimizer style was the most responsive to training in creative problems solving. Michael Kirton described a measure of adaptor and innovator styles that is often used. Gerard Puccio et al., for example, used it and found relationships with self-reports of creative products.

As Puccio et al. put it (in the 2009 *Creativity Research Journal*), "the adaptive orientation was linked to products that were described as logical, adequate, well-crafted, and useful.... the innovative style was highly related to product characteristics such as original, attractive, transformational, and expressive" (p. 157). The key tenant of the styles approach is that there are different ways to be creative. Creativity is possible using more than one style.

Multivariate Theories

Several theories of creativity have predicted an interplay among processes. This approach makes a great deal of sense because behavior in the natural environment is rarely dependent on one process or skill. Creativity in particular is likely to be multivariate. Recall here the idea of a creativity complex or syndrome.

Sternberg (2006) took an economic approach to creativity. He described how creators "buy low and sell high," which is essentially a contrarian tactic, and he had developed a model of creativity that describes the use of six resources, namely intellectual ability, styles of thinking, knowledge, motivation personality, and environment. Sternberg (2006, p. 6) concluded that "although levels of these resources are sources of individual differences, often the decision to use the resources is the more important source of individual differences." Runco, Johnson, and Gaynor (1999) had reached a similar conclusion and also argued that decision-making represents the most important part of creative behavior. They found illustrations of this in individuals deciding what to study, how to invest their time, what to ignore, who to read, what career to pursue, where to pursue it, and even what ideas and solutions to examine and share with others. Decisions about where to work may come as a surprise, but then again, this makes an enormous amount of sense given what we now know about geographic distributions and creativity (Florida, 2002). Decisions about what solutions and ideas to pursue are also extremely important, especially given what was noted above, that original ideas are remote (Mednick, 1962). Such remote and creative ideas will not be found unless the individual chooses to persist in exploring a particular line of thought. Without a doubt many individual differences in creativity reflect variations in the decision-making process.

Conclusions

Individual differences in creativity have been described in terms of key traits, cognitive skills, styles, attitudes, decision-making, and even the use of resources. This range is necessary because creativity is a complex. Recall also the important point that there are different ways to be creative. This implies not only that a person can be creative in art or mathematics or science or some other domain, but also that individuals may be creative with one style, or with a very different style. The same can be said about the different traits, though this does remind us that the most realistic view of individual differences in creativity is probably that which recognizes an interplay between personality, cognition, and extra-cognitive processes. All of this underscores the importance of individual differences for

the understanding of creativity. After all, saying that there are different ways to be creative assumes that there are individual differences.

There is intriguing agreement among the different kinds of research. Openness, risk taking, and contrarianism, for instance, are each used in the personality research, the cognitive research, and the research on attitudes. Independence and risk taking are also found in different kinds of research on creativity. In addition, the neurosciences are now being employed and very likely these will soon uncover relevant individual differences. One step in this direction involves dopamine, which both shows individual differences and a correlation with certain indicators of creative potential. And although a number of interactions were mentioned in this chapter (especially in the section devoted to multivariate approaches), research examining the interaction and interplay of the various dimensions and factors is still sorely needed. Given the value placed on creativity, for problem solving, health, and progress, there is no doubt that the study of individual differences in creativity will continue, with great benefit for many disciplines and domains.

Individual Differences in Employee Performance

Richard A. Currie, Victoria L. Pace, and Krystyn J. Ramdial

University of Central Florida

With the ever-increasing use of technology in employment selection, organizations receive several times as many applicants for one job posting as were received one decade ago. Understanding the links between individual differences (e.g. cognitive ability and personality) and job-related performance can assist in the screening and selection process as well as in performance management.

Job-Related Performance

Although task performance (i.e. completing the explicit role requirements of the job) is frequently studied in organizational research, employers are increasingly interested in selecting employees who can also effectively perform tasks not explicitly outlined in employees' job descriptions. In addition to task performance, other highly relevant forms of performance include adaptive performance (i.e. adapting well to organizational change), team member performance (i.e. working well within workgroups), training performance (i.e. proficiency in training programs), and contextual performance (i.e. exhibiting organizational citizenship behavior, OCB). Additionally, effective performance as an organizational leader requires a separate set of skills and traits than those needed for lower-status jobs. These distinct aspects of job-related performance are discussed due to their relevance to organizations.

Predicting Job-Related Performance

Much research has found that general cognitive ability is the best predictor of job performance across employment contexts. However, others have found that cognitive ability tests exhibit high rates of adverse (discriminatory) impact against racial minority members and can result in expensive, reputationally damaging federal lawsuits against organizations.

Thus, employee selection personnel are asked to implement relatively inexpensive, valid methods of predicting employee job-related performance, that exhibit little to no discrimination.

Big Five Personality Model

To avoid some of the negative outcomes associated with the use of cognitive ability measures, some have gravitated toward using personality traits as predictors of job-related performance. Personality is frequently described as broad patterns of behavior that exhibit relative consistency across time and place. Although several classifications of personality exist, the five-factor model, often referred to as the "Big Five," is the dominant taxonomy of normal personality. As suggested in its name, the Big Five consists of five individual factors, or dimensions, of personality, namely agreeableness, conscientiousness, emotional stability (the opposite of neuroticism), extraversion, and openness to experience. Prior empirical evidence has found weak correlations among the five factors, suggesting that each dimension captures distinct aspects of personality. Furthermore, there is evidence of weak correlation between personality and cognitive ability, suggesting that these two constructs measure different attributes.

Personality in Employment Decision-Making

Guion and Gottier (1965), in their review of the validity of personality measures in employment selection, concluded that personality measures exhibit little value as predictors of job-related performance. However, more recent research suggests quite the contrary (Barrick & Mount, 1991; Hogan & Holland, 2003). Although each of the five factors has been shown to relate to the broad construct of job-related performance, some of the factors have been shown to be better predictors of general task performance, whereas others have been shown to predict specific job criteria. The following sections briefly describe the Big Five factors of personality and present research linking each factor to several aspects of job-related performance.

Conscientiousness

Conscientiousness is the personality trait associated with responsibility, dependability, timeliness, attention to detail, and achievement-oriented attributes (Barrick & Mount, 2012). It is widely known that conscientiousness is the Big Five personality factor exhibiting the strongest relationship to task performance across nearly all jobs (Barrick & Mount, 1991, 2012). Prior research, however, suggests that highly conscientious employees may exhibit less creativity than those with moderate to low levels of the trait (Barrick & Mount, 2012; Hough, 1992). Nonetheless, meta-analytic evidence suggests that conscientious employees adapt well to organizational change (Huang, Ryan, Zabel, & Palmer, 2014), conscientious leaders engage in transformational leadership (Bono & Judge, 2004), and conscientiousness is the Big Five personality trait with the strongest relationship to overall OCB (Chiaburu, Oh, Berry, Li, & Gardner, 2011).

Emotional Stability

Individuals with high levels of emotional stability (low levels of neuroticism) are typically calm, relaxed, and do not show high emotional reactivity to normal day-to-day stressors. Similar to conscientiousness, prior research has found emotional stability to relate positively to job performance across work contexts (Barrick & Mount, 2012). Meta-analytic evidence found that, among the Big Five factors, emotional stability exhibited the strongest relationship with adaptive performance (Huang et al., 2014), and that emotional stability is tied with agreeableness as the Big Five personality trait with the second-strongest relationship with general OCB (Chiaburu et al., 2011). Moreover, Bono and Judge (2004) found a significant, positive relationship between emotional stability and transformational leadership.

Extraversion

Extraversion is the Big Five personality trait most associated with sociability and outgoingness. Unlike conscientiousness and emotional stability, extraversion has not been shown to predict overall job performance across jobs. Furthermore, Chiaburu et al. (2011) found a nonsignificant relationship between extraverted employees and engagement in overall OCB. Nonetheless, previous research examining extraversion has found that it relates to other important forms of job-related performance. For example, meta-analytic evidence found that extraversion has the strongest relationship with transformational leadership relative to the other Big Five factors (Bono & Judge, 2004). Barrick and Mount (1991) concluded extraverted employees exhibit superior training performance relative to introverted employees. Additionally, Mount, Barrick, and Stewart (1998) found that extraversion is a stronger predictor of performance in jobs involving teamwork relative to jobs involving low interpersonal interaction.

Agreeableness

Highly agreeable individuals are likely to be compassionate, caring, and nonargumentative (Barrick & Mount, 2012). Agreeableness has also not been shown to be a generalizable predictor of job performance. Moreover, Bono and Judge (2004) discovered that agreeableness did not have a significant relationship with transformational leadership. However, agreeable employees can benefit organizations in several important ways. For example, research suggests that agreeable employees perform better in team-based jobs relative to jobs requiring little to no interpersonal interaction (Mount et al., 1998). Furthermore, employees higher in agreeableness have also been shown to engage in more OCBs (Chiaburu et al., 2011).

Openness to Experience

The final factor of the Big Five, openness to experience, is the personality trait associated with artistic-mindedness and inquisitiveness. Despite the prominence of Big Five taxonomy in organizational research, much less attention is afforded openness to experience than the other four Big Five factors. Perhaps this is because many empirical studies have found nonsignificant relationships between openness to experience and task performance. Additionally, the meta-analysis by Huang et al. (2014) found that openness to experience did not significantly relate to employee adaptive performance. Despite these findings, other research has found that openness to experience is, in fact, a valid predictor of job-related

performance constructs, including innovative performance (Hammond, Neff, Farr, Schwall, & Zhao, 2011), creative work performance (Pace & Brannick, 2010), training performance (Barrick & Mount, 1991), and OCB (Chiaburu et al., 2011). Hence, employees with high levels of openness to experience can be quite valuable organizational assets.

Other Personality-Related Traits

Although the Big Five personality model is the most widely used taxonomy of normal personality in organizational research, other personality-related individual difference traits have also been shown to predict job-related performance. Core self-evaluations, which are comprised of self-esteem, generalized self-efficacy, locus of control, and emotional stability, have been described as basic appraisals that people have of themselves (Judge & Bono, 2001). Prior meta-analytic evidence by Judge and Bono (2001) found that not only are core self-evaluations positively related to job performance, but that each of the four components of core self-evaluations positively relate to both job satisfaction and job performance. Additionally, prior empirical evidence suggests that trait competitiveness positively relates to both learning effort and performance in sales-oriented roles (Wang & Netemyer, 2002). Lastly, emotional intelligence, which is described as the capacity to use one's own emotions and the interpretation of others' emotions to inform one's thinking, is an individual difference characteristic that has recently received substantial theoretical and empirical research attention. Specifically, emotional intelligence has been shown to positively relate to job performance (Joseph, Jin, Newman, & O'Boyle, 2015).

Limitations and Future Directions

Although there is a sizable literature on personality in relation to job-related performance indicators, there are notable limitations of using personality assessments in personnel decision-making contexts. Primarily, researchers and practitioners are wary of the increased prevalence of faking on personality assessments due to social desirability bias and self-monitoring processes. Since faking can decrease the reliability and validity of personality assessments, researchers have examined several techniques (e.g. conditional reasoning tests, forced-choice formats, warnings) to mitigate faking. However, there is mixed support for the effectiveness of such methods. Thus, an important future research direction is to improve existing counter-faking techniques as well as develop novel approaches to mitigate faking. Additionally, researchers ought to consider exploring curvilinear relationships between personality traits and job-related performance domains. For example, Mudrack, Bloodgood, and Turnley (2012) found evidence that too much competitiveness can be counterproductive in team settings. Therefore, it is worth examining whether extreme levels of other personality traits (e.g. extraversion, agreeableness, etc.) can also exhibit counterproductive effects.

Overall, the use of personality assessments in employment decision-making has received wide theoretical and empirical research support. Furthermore, in using personality tests in the employment decision-making process, organizations can avoid some of the pitfalls associated with the use of other methods, while, at the same time, maintaining confidence in their ability to select highly valuable employees.

Emotional Intelligence in the Workplace

Neal M. Ashkanasy[1] and Catherine S. Daus[2]

[1]*University of Queensland*
[2]*Southern Illinois University, Edwardsville*

Although initially developed for application in educational settings, the concept of emotional intelligence was quickly adapted by both scholars and practitioners and applied to workplace settings, stimulated to a large extent by popular books authored by *New York Times* columnist Daniel Goleman, and with particular focus on its role in leadership. Almost immediately, however, the construct came under attack, especially from scholars of social and industrial-organizational psychology, and especially by scholars of leadership. In this entry, discussion is based on two articles written in response to criticism of the construct. In the first (Ashkanasy & Daus, 2005), the authors proposed that there are three "streams" of emotional intelligence scholarship. *Stream 1* refers to the concept as defined in Mayer and Salovey (1997) and measured using the MSCEIT (Mayer-Salovey-Caruso Emotional Intelligence Test) or other measures of ability, similar to measures of IQ; *Stream 2* refers to the concept as defined by its originators (Mayer & Salovey, 1997), but utilizes measures employing self- or peer-report methodology; *Stream 3* refers to alternative definitions of emotional intelligence typically also using self- or peer-report measures. The second (Daus & Ashkanasy, 2005) presented the case for the ability model in organizational behavior research. In the reminder of this entry, each of the three streams is addressed in turn.

Stream 1

"Stream 1" refers to the so-called "ability perspective" of emotional intelligence, in which the construct is construed as a specific constellation of mental skills and abilities that develop over time. The concept, originally defined in 1990 as "the ability to monitor one's own and others' feelings and emotions, to discriminate among them and to use this information to guide one's thinking and actions" (Salovey & Mayer, 1990; p. 189), has evolved and broadened over the last 25 years. Within the Stream 1 perspective, contemporary scholars refer to the "four-branch" ability model defined by Mayer and Salovey in 1997. These

branches are hierarchically arranged from most basic to most complex: (1) perception of emotion; (2) use of emotion to facilitate thought; (3) understanding of emotion; and (4) management of emotion.

Perception of emotion involves identifying accurately discrete emotions in self and others. *Use of emotion to facilitate thought* includes the ability to be able to use emotions to direct attention to critical information about events, persons, and the environment to help make accurate judgments and decisions. As well, this branch involves using emotion to assist reasoning and problem solving. *Understanding emotion* is having knowledge of the predictors of discrete emotions, including how they change (e.g. are amplified or suppressed). Subsumed in this is the skill verbally to label emotions appropriately, and be able to distinguish between similar but distinct emotions (e.g. regret and guilt). Finally, *management of emotion* includes regulating emotions in self and others. This also comprises being able to stay open to experiencing a variety of emotions as well as engaging or detaching from emotions appropriate to the context.

Emotional intelligence as an ability has been found empirically to be related moderately to other types of intelligences, and weakly-to-moderately related to personality structures such as the Big Five (openness, conscientiousness, extroversion, agreeableness, emotional stability). Of these, the only trait that shows more than a weak relationship with ability emotional intelligence is agreeableness, which has a small amount of conceptual overlap (Mayer, Roberts, & Barsade 2008). There is also evidence that ability emotional intelligence is inversely associated with Machiavellianism. Ability emotional intelligence has thus demonstrated definitive and appropriate discriminant and convergent construct validity.

Importantly, ability emotional intelligence has been found empirically to predict a variety of life outcomes. Regarding psychological health and well-being, emotional intelligence as an ability is negatively related to anxiety and depression and symptoms of schizophrenia; and positively related to well-being and seeking treatment when needed.

Emotional intelligence as an ability also predicts children's social and psychological health and well-being, as well as academic performance, including problems – both social and academic – at school. While there is mixed evidence regarding academic performance of high school and college-aged individuals and emotional intelligence, there is consistent evidence that, with younger children, ability emotional intelligence predicts attention and learning, and positive attitudes toward school.

Moreover, a plethora of evidence supports the idea that those higher in ability emotional intelligence fare better socially and have more positive social functioning. Quite simply, these people have more friends, better social support systems, and generally higher quality relationships, both romantic and platonic. Moreover, ability emotional intelligence consistently negatively predicts poor life choices regarding destructive and addictive behaviors such as nicotine, drug, and alcohol use, stealing, and fighting.

Finally, regarding emotional intelligence as an ability in applied domains, the work environment has been studied extensively regarding how ability emotional intelligence plays out. Generally, regarding work performance, positive relationships have been found with ability emotional intelligence.

Conversely, however, recent evidence suggests a potential performance downside to some aspects of emotional intelligence. For example, the emotionally intelligent, just like the traditionally cognitively intelligent, may use their abilities for personal gain, to

manipulate and to get ahead in an organizational setting. The negative relationship mentioned earlier regarding ability emotional intelligence and Machiavellianism is contrary to this suggestion, however.

Stream 2

Stream 2 models of emotional intelligence include self- and peer-report measures that the authors claim are based in either Salovey and Mayer's (1990) three-dimensional model, or the more recent "four-branch" model of emotional intelligence (Mayer & Salovey, 1997). Examples of this genre include the Schutte Self Report Emotional Intelligence Test (SSEIT: Schutte et al., 1998), the Wong and Law Emotional Intelligence Scale (WLEIS: Wong & Law, 2002), and the Workgroup Emotional Intelligence Profile (WEIP: Jordan, Ashkanasy, Härtel, & Hooper, 2002). Among them, these three articles have been cited more than 4,200, 8,600 times in Google Scholar® at the time of writing. The popularity of these measures derives from the fact that they are relatively short (usually) self-report scales, easily administered either in hardcopy or online forms, and are available for use in the public domain. A further issue is that, while the scales are normally administered in self-report format, they are based in the original model of emotional intelligence put forward by the construct's originators.

Although the three Stream 2 scales are purportedly based in the work of Mayer and Salovey, following factor analysis, the authors of all three scales reported that their scales essentially measure four (different) dimensions: (1) appraisal and expression of emotion in self; (2) regulation of emotion in self; (3) use of emotion to facilitate thinking; and (4) recognizing and managing emotion in others (see Table 1 for a summary).

Nonetheless, and despite concerns that they are subject to common method issues, the Stream 2 measures seem to perform consistently well in meta-analytic studies. The measures have also been successfully used to demonstrate that emotional intelligence is associated with team performance rather than individual decision-making performance.

Table 1 Dimensionality of Three Stream 2 Measures.

SSEIT (Schutte Self Report Emotional Intelligence Test)	WLEIS (Wong and Law Emotional Intelligence Scale)	WEIP (Workgroup Emotional Intelligence Profile)
1) Appraisal and expression of emotion	1) Self-emotion appraisal	1) Aware of own emotion
2) Regulation of emotion in the self	2) Regulation of emotion in self	2) Discuss own emotion
3) Utilization of emotion	3) Uses of emotion	3) Emotions facilitate thinking
4) Regulation of emotion in others	5) Others' emotion appraisal	4) Recognize others' emotion
		5) Detect false emotions
		6) Empathy
		7) Manage others' emotion

Stream 3

Measures of emotional intelligence classified in Ashkanasy and Daus (2005) as "Stream 3" use self- and peer-reports similar to the Stream 2 measures, but they are *not* based on Mayer and Salovey's original definitions of emotional intelligence. Well-known examples include the Goleman's Emotional Competence Inventory (ECI: Hay Group, 2005), the Bar-On's (1997) EQ-i™, Petrides, Frederickson, and Furnham's (2004) Trait Emotional Intelligence Questionnaire (TEIQue), and Genos™ (Gignac, 2001; Palmer, Stough, Harmer, & Gignac, 2009).

Although widely used, especially as consulting tools, the main question surrounding these measures is what they represent. The authors of these measures all claim that they measure "real" emotional intelligence, and make strong claims for the predictive validity of their scales, but this is most likely because of their strong overlap with personality measures; for example meta-correlations as high as r = .85 has been reported. Given that the Genos measure was originally developed by factor-analyzing a collection of personality measures, however, this is hardly surprising. Similarly, the EQ-I began life as a form of sub-clinical personality assessment for Bar-On's doctoral dissertation on psychological well-being and alexithymia (inability to identify emotions in the self). As Ashkanasy and Daus (2005) point out, Bar-On recognized the potential for his measure to be used for emotional intelligence only after reading Goleman's best-selling book on the topic.

In terms of dimensional structure, and as can be seen in In Table 2, the Stream 3 measures all share some commonality with Stream 2. For example, all include sub-scales to measure emotional self-awareness and emotional regulation. Also clear from the table, however, is that the scales tap into a wide variety of additional social competencies, including inspirational leadership (ECI), problem solving (EQ-i), stress management (TEIQue), and emotional reasoning (Genos). Given the wide range of these constructs combined with their overlap with personality, it is no wonder therefore that Stream 3 measures appear to have broader predictive validity than either Stream 1 or Stream 2 measures.

Conclusions

In this entry, emotional intelligence and its applications in workplace settings is discussed from three perspectives corresponding to the three "streams" of emotional intelligence research identified in Ashkanasy and Daus (2005). Streams 1 and 2 are based on the Mayer and Salovey (1997) "four-branch" definition of emotional intelligence that is generally recognized as the preeminent definition of the construct. Stream 2 measures differ from Stream 1 insofar as they rely on self- or peer-ratings of emotional intelligence, as opposed to Stream 1, which is based on the MSCEIT or other ability measures. Stream 3 models of emotional intelligence, while ostensibly performing well in terms of predictive tests, in fact most likely only do so because of their documented overlap with personality measures. As such, it is recommended that scholars steer clear of Stream 3 approaches, especially if their interest is in measuring and/or applying the construct of emotional intelligence as defined by its originators.

Table 2 Dimensionality of Four Stream 3 Measures.

ECI (Emotional Competence Inventory)	EQ-i™	TEIQue (Trait Emotional Intelligence Questionnaire)	Genos™
1) Emotional self-awareness	1) Self-regard	1) Adaptability	1) Emotional self-awareness

Alliant International University

Introduction

Leadership is the key to organizational effectiveness. It is the art of providing vision, understanding and maximizing the talents of each follower, and inspiring followers to contribute toward achieving a common goal. Effective leadership is associated with competencies such as good listening and mentoring skills, goal-setting, problem solving, and ethical decision-making, as well as with certain personality traits such as extraversion and conscientiousness. The combination of individual traits and qualities forms a leader's distinct personality character, and is associated with his/her leadership approach and style.

An evolutionary perspective of leadership argues that since human beings are naturally selfish, they will only allow a person to lead if it is advantageous to their survival. As such, people must be able to assess and identify leaders who possess key leadership traits and who can ensure the group's survival. Since individual differences are directly related to group dynamics and performance, certain personalities may be better equipped to lead than others.

There is an ongoing debate about whether leaders are born with personality characteristics that set them apart from followers or whether anyone can develop to become a leader under the right circumstances and training. The trait-based perspective argues that certain innate characteristics make people suitable for leadership. The Great Man Theory, a popular nineteenth-century approach, assumed that great leaders are born, not trained; they acquire heroic and powerful male qualities. Research in the mid-1900s focused mainly on the relationship between basic personality characteristics and leadership. Later, McCrea and Terraccino (2005) studied people from more than 50 countries and found that the Big Five traits (extraversion, conscientiousness, openness to experience, agreeableness and neuroticism) are universal and can be used to accurately describe the personality of leaders. Recently, researchers have focused on more specific traits such as intelligence, self-confidence, determination, sociability and integrity that relate to effective leadership.

While the trait-based approach posits that a person who does not have the "right personality" cannot become a leader, behavior-based approaches argue that anyone can develop certain behaviors and/or competencies which can lead to effective leadership. Incorporating Skinner's theory of behavior modification through reward and punishment, the Ohio State Studies in the late 1940s identified independent dimensions of leader behavior, which were narrowed down to initiating structure (i.e. defining roles and tasks, and organizing work) and consideration (i.e. demonstrating concern for group members). Other studies followed a similar approach (e.g. University of Michigan studies). Overall, studies found that leaders high on both dimensions tend to achieve high follower performance and satisfaction. However, one limitation was the lack of consideration for situational factors, which could explain the absence of a consistent relationship between these behavioral dimensions and group performance.

Understanding effective leadership is more complex than isolating a few traits or behaviors. Awareness of critical situational influences on leadership effectiveness, such as leader-member relations, position power, role clarity, group norms, and information availability, led to the development of the contingency theories in the late twentieth century. The most comprehensive was developed by Fiedler (1967), who proposed that leader styles must match task structure, leader-member relations, and the leader's ability to administer rewards and punishment. Other contingency theories followed, including Hersey and Blanchard's Situational Leadership Theory (1969), Graen and colleagues' Leader-Member Exchange Theory (1982), and House's Path-Goal Theory (1971).

A leader with a personality type associated with certain characteristics is more likely to prefer a certain leadership approach. For example, extraverted managers may find it easier to lead meetings, confront presentations, and lead change. Despite diverse approaches to leadership, it is generally acknowledged that leader personality influences his/her leadership style, which in turn influences interpersonal and team dynamics, and ultimately organizational outcomes.

When we refer to personality's effect on leadership, we generally consider its impact on leader emergence (i.e. the assumption of leadership in a group) and leader effectiveness (i.e. the leader's ability to build a successful team or organization). In the next section, we summarize key findings of past research related to personality and leadership emergence, effectiveness, and style.

Personality and Leadership Emergence

Leadership emergence refers to being perceived as a leader and being motivated to lead. Leaders who emerge in a group exhibit certain personality characteristics. Extraversion, openness to experience, conscientiousness, emotional stability, authoritarianism, creativity, masculinity, antagonism, self-esteem/efficacy, and social skills have all been found to strongly predict emergence, albeit the magnitude of the overall effect was moderate (e.g. Judge, Bono, Ilies, & Gerhardt, 2002). Although agreeableness does not predict emergence, it does predict the emergence of relationship-oriented leaders whereas extraversion, openness to experience, and conscientiousness predict the emergence of task-oriented leaders (Emery, Calvard, & Pierce, 2013).

Personality also impacts motivation to lead (MTL). Some people devote more energy and resources to becoming a leader in various situations. MTL has three main components: affective, social-normative, and non-calculative. Affective MTL refers to enjoying leading. Social-normative MTL defines people who believe it their duty to lead. Non-calculative people have no desire to lead. People who enjoy leading and who consider leadership as their duty tend to be outgoing and sociable by nature (i.e. extraverted) and are confident in their own leadership abilities (i.e. have high self-efficacy) (Chan & Drasgow, 2001).

Personality and Leadership Effectiveness

Just because someone emerges as a leader does not necessarily mean s/he will be effective. Estimates of managerial failure have been as high as 50%, suggesting that at least half of all leaders emerge and then perform poorly. Research shows that all Big Five personality traits, as well as achievement motivation, energy, dominance, honesty/integrity, self-confidence, and creativity predict leader effectiveness (Hoffman, Woehr, Maldagen-Youngjohn, & Lyons, 2011).

While most studies have operationalized effectiveness as perceived performance at work, some research has used more objective measures of leadership effectiveness, such as group and organizational performance outcomes. For example, Boone, de Brabander, and Hellemans (2000) found that CEO internal locus of control positively predicted company performance indicators, including cash flow on assets, return on assets, price-cost margin, and labor productivity in small- to medium-sized companies.

While trait-based approaches have mainly focused on positive leadership traits, "dark side" personality traits, which represent negative leadership attributes, have also been studied. These are often not apparent during an initial meeting when first impressions are made, and thus are difficult to detect when selecting individuals for leadership roles. Although these dark side traits (e.g. narcissism, psychopathy, and Machiavellianism) may not inhibit day-to-day functioning, they can cause undesirable social interaction, and negatively predict overall managerial performance and critical managerial work behaviors (Gaddis & Foster, 2015).

Personality and Leadership Styles

Past approaches neglected the complexity of leadership processes and the context in which they operate. More contemporary research focused on combinations of traits, behaviors, and styles which are stronger predictors of leadership than individual traits. While the most commonly known leadership styles are authoritarian, democratic, and laissez faire, contemporary research on personality and leadership styles has mainly focused on transformational, transactional, ethical, servant, and authentic leadership styles, which are briefly summarized below.

Leadership expert Burns (1978) defined transformational leadership as a process where "leaders and their followers raise one another to higher levels of morality and motivation" (p. 83). Transformational leaders exhibit four characteristics: idealized influence (high

ethical standards, engendering loyalty and respect); inspirational motivation (communicates a compelling vision based on values and ideals); intellectual stimulation (challenges norms and encourages creative solutions); and individual consideration (develops, coaches, and consults with followers). Transactional leaders, on the other hand, focus on monitoring and controlling employees, and taking corrective action as necessary.

Both styles have been linked to the Big Five personality factors. Extraversion showed robust relations with both leadership outcomes and leadership behaviors. CEOs who are more emotionally stable and open to experience are more likely to exhibit transformational leadership behaviors, which subsequently enhances employee commitment and overall organizational performance (Colbert, Barrick, & Bradley, 2014). Although ratings of transactional leadership behaviors were less strongly related to personality, agreeableness, extraversion, and neuroticism positively predicted aspects of transactional leadership (Bono & Judge, 2004). While these studies discovered the dispositional basis of these styles, there was substantial variability across studies, suggesting that future research must focus on narrower personality traits and situational characteristics.

Ethical leadership is a style characterized by integrity and ethical conduct that is, in turn, embraced by followers who emulate these behaviors, and is associated with positive outcomes such as job satisfaction, organizational commitment, and task performance. People high on agreeableness, conscientiousness, extraversion, and emotional stability are more likely to exhibit ethical leadership behaviors (Kalshoven, Den Hartog, & De Hoogh, 2011).

Servant leadership is another moral leadership concept characterized by the fundamental view of the leader as servant to others. Servant-led organizations manifest greater trust in the leader and the organization, organizational citizenship behavior, procedural justice, team and leader collaboration, and overall effectiveness. Perceptions of servant leadership were positively related to agreeableness and negatively related to extraversion (Hunter, Neubert, Perry, Witt, Penney, & Weinberger, 2013).

Finally, authentic leadership has garnered increased attention over the past decade, having been linked with several positive follower and organizational outcomes. It is characterized by self-awareness and consistency among one's identity, beliefs, and behaviors (Gardner, Cogliser, Davis, & Dickens, 2011). Despite a paucity of research linking personality to authentic leadership, authentic leaders act in accordance with their own personality so as to be authentically perceived by themselves and others. It is important for future research to investigate its personality antecedents.

Conclusion

The focus on personality and leadership has waxed and waned over the last 100 years. The idea that people are born with certain traits predisposing them to become leaders was not consistently supported by early studies. Bivariate correlations between specific traits and leadership were small, if not significant, making the applicability of the trait approach limited. This led to the rise of other approaches combining individual characteristics and behaviors as distinctive leadership styles.

With the advent of sophisticated meta-analytic and modeling techniques, recent studies have demonstrated that, upon statistical correction, personality variables do have a

moderate impact on leadership outcomes. For example, Judge et al.'s meta-analysis (2002) found a multiple correlation of .48 between the Big Five personality traits and leadership. Additionally, more studies are incorporating personality traits as either antecedents or moderators of the relationship between state-based characteristics and behaviors, and different leadership outcomes. Many of the broader leadership perspectives, such as transformational and ethical leadership, incorporate specific personality attributes as important aspects of said styles. A number of personality traits, such as openness to experience and tolerance for ambiguity, also enable leaders to adapt to situational changes. Similarly, emotional intelligence as a trait has garnered attention among researchers and practitioners, especially with regard to how leaders can utilize awareness of self and others to regulate emotions and interact effectively with others (e.g. Roy, 2015).

In sum, the contemporary discussion of personality and leadership has moved beyond whether (and which) traits predict leadership to how personality variables influence leadership behaviors, training, and coaching through various mechanisms, and how these occur in diverse situations.

Applications

Personality assessments are commonly used to identify leader potential and readiness within talent selection and development programs. Evidence from personality research is useful for matching individuals to certain jobs and roles. Personality traits are foundational attributes that likely predispose leaders to display certain mindsets or behaviors, as well as develop knowledge, skills, and abilities in response to specific scenarios. However, scoring high on a particular trait such as extraversion does not mean that scoring low necessarily prevents one from being a good leader. In fact, it has been argued that introverts could be great supervisors because they are good listeners and tend to be very thoughtful (Cain, 2012). Overall, whether personality attributes contribute to actual success depends on the type of organization, organizational level, and other follower and contextual characteristics.

Another application is the use of personality assessments for personal and professional development. Leaders could leverage existing traits or alter personal attributes through personal reflection, coaching, mentoring, training, and other targeted interventions. While a debate remains about the extent to which personality is malleable, new evidence suggests that personality is fluid, despite change occurring slowly or perhaps not at all for some individuals (Roberts & Mroczek, 2008). Leaders with a deeper understanding of their own personality, thoughts, emotions, values, and motives are better able to adapt their behavior and leadership style to be more compatible with specific situations, while identifying ways to utilize their natural strengths in the workplace.

Future Directions

Personality is important to the leadership puzzle but it is not the only piece. Future research should consider integrative frameworks that link personality and other attributes (e.g. cognition, motives, values, demographics), with specific skills, behaviors, and other mechanisms

(e.g. attribution and leader-follower identification processes). The interaction of these factors and their effect on diverse leader effectiveness outcomes should take contextual elements into account. A number of such integrative models have been proposed for further empirical investigation (e.g. Zaccaro 2007). Within such frameworks, researchers can consider a broader set of outcomes, examining subjective, as well as objective, measures of leader performance at the individual, dyad, group, and organizational levels.

Moreover, it is important to look at the relationships among personality, culture, and leader effectiveness in today's global environment. The GLOBE project (House, Hanges, Javidan, Dorfman, & Gupta, 2004), the most extensive research on leadership and societal values, has found that certain leadership traits are universally acceptable (e.g. decisiveness, honesty, team-builder, intelligence, and excellence-oriented), while others are universally unacceptable (e.g. ruthless, egocentric, non-cooperative) or culturally contingent (e.g. enthusiastic, compassionate, risk-taking). GLOBE researchers also highlight the importance of tolerance for ambiguity, cultural flexibility, and a global mindset. Further research should examine whether these attributes actually predict global leadership effectiveness.

Finally, as the study of leadership expands from a "Great Man" lens to alternative conceptualizations, it is important to look at feminine perspectives as well as collective notions of leadership. Examining the personality configurations among followers or team members could also shed light on how to form and maximize the performance of leadership teams.

Leadership has been a topic of contentious debate since the time of the ancient philosophers. In the nineteenth century, philosophers explored the ways in which individuals gain and maintain leadership positions. With the emergence of psychology as a discipline, theories of leadership became more focused on individuals. Over the years, researchers have explored leadership from a number of different perspectives including behavioral, trait, and to a much lesser extent contextual. These elements generated a number of different, sometimes conflicting leadership theories. In the twenty-first century, researchers are exploring the need for new leadership prototypes to fit the changing world demographics.

Leadership Theories

Leadership psychology has its roots in the same era that the discipline of psychology was formed. Upon examining influential figures in history, philosophers of the nineteenth century developed what is known as the Great Man Theory (GMT). This theory states that a person would achieve a leadership position based on favorable qualities such as charisma, intelligence, and wisdom. Criticism of this theory argues that it fails to acknowledge the effects of outside influences on a leader's behavior. Though largely discredited due to its restrictive nature, the GMT became a framework for future ideas and research into what constitutes a leader.

The study of human personality and heritability gave rise to the investigation of differences between people's traits. In the 1920s and 1930s trait theory surfaced as a dominant paradigm in personality psychology, and thus heavily influenced leadership studies. Trait psychologists looked to the traits that differentiated leaders from nonleaders. Neglectful of early GMT criticism, trait theorists believed that the qualities and abilities that comprise a leader are inherent or innate to that individual. In other words, there are some traits that are more suitable for leadership than others. Trait leadership explores the influence of

certain traits and what they are rather than the behavior that makes them a leader. Trait theory evolved to focus on specific components of leadership that can be associated and attributed to a leader to determine their effectiveness.

Critiques of GMT and development of trait theory gave rise to the attempt to understand leadership from a behavioral perspective. Behavioral leadership techniques focus on the principle that a leader can be conditioned and taught to lead effectively as opposed to having the innate ability to lead as seen in trait theory. Favorable leadership traits are understood as behaviors and are applied through learning processes rather than identifying and isolating them within a person. Behavioral theories gave way to the use of training programs in the workplace to condition leaders with the behaviors seen as most effective and beneficial to the company.

In the 1940s and 1950s, two groundbreaking studies in behavioral leadership emerged in the field. Ralph Stodgill used 1800 leadership related statements with nine leadership dimensions to create the Leadership Behavior Description Questionnaire (LBDQ). The LBDQ was administered to a variety of groups including college students and faculty as well as military personnel. Stodgill found that not only is there no consistent pattern of traits among leaders but also that there were two distinct leadership types: consideration (people oriented) and initiating structure (task oriented) (1948). This inability to quantify traits among leaders rendered the GMT an incompetent assessment of leadership. In the GMT's place, behavioral styles like consideration and initiating structure provided a fresher understanding of leadership.

Contingency theories of leadership generally rely on the notion that a leader's effectiveness depends on numerous factors such as their personality, the work environment/culture, and the followers. Fred Fielder pioneered this theory in 1958 with his least preferred coworker scale (LPC), which is used to ask a leader which traits they find the least appealing in a coworker. Low LPC scores represent a task-driven leader while high LPC scores represent a relationship-focused leader.

Leadership Styles

German-American psychologist Kurt Lewin, known for his pioneering social, organizational, and applied psychological inquiries, was at the forefront of contemporary leadership psychology. He and his colleagues (Lewin, Lippit, & White, 1939) conducted numerous experiments concerning decision-making styles and their influence on three different styles of leadership:

- *Autocratic*: leader makes executive decisions without consultation of followers.
- *Democratic*: followers are involved in decision-making but leader makes final decision based on group consensus.
- *Laissez-Faire*: minimal decision-making by the leader, followers make decisions on their own and deal with consequences on their own.

Transactional leadership is a managerial style focusing on the "help me help you" agreement between the leader and the follower. The leader either uses contingent rewards (explaining what must be done to gain a reward) or passive management by exception

(using corrective techniques if follower behavior is substandard). The style is based on behavioral assumptions that individuals will follow in order to meet survival needs (longer hours for larger paycheck) and that leaders will operate within their environment and culture. Despite research demonstrating its relative ineffectiveness, this style is still popular today.

According to James Macgregor Burns, transformational leadership (TF) is based on the idea that a leader should go beyond the exchange of bare living essentials and inspire followers to change their lives for the better. Burns criticized the simplicity of transactional leadership and its lack of fulfillment for the followers. Burns pointed to leaders such as Gandhi, Martin Luther King, Jr., John F. Kennedy, and Franklin D. Roosevelt who transformed not only many lives but also the culture and environment in which they existed. Burns emphasizes that leaders raise the ethical and moral standards, energize followers with their own empowerment, and promote corporate responsibility. Bernard M. Bass believed that TF leaders should focus on intrinsic motivation and positive development of followers, raising awareness of moral standards, clarifying goals, ethical climate/ethical standards, and encouragement to look beyond self-interest, appeal based on reason, and allowing freedom of choice.

Bass challenged Burns's notion that a leader was either transactional or TF claiming that leaders use both styles. Bass's approach includes four TF leadership components that are commonly referred to as the Four Is:

- *Idealized influence:* match the follower's leadership prototype, be a role model they can respect, admire, and trust, put others' needs before their own, and behave consistently with values and principles of the group.
- *Inspirational motivation:* motivate by providing meaning and challenge to follower's tasks, arouse team spirit/cooperation, be enthusiastic and optimistic, and create desirable visions for the future.
- *Intellectual stimulation:* stimulate innovation and creativity by encouraging followers to question assumptions, reframe situations, and approach old problems from new perspectives.
- *Individualized consideration:* act as coaches or mentors that foster personal development, provide learning opportunities in a supportive climate for growth, and tailor to the individual needs and desires of each follower.

The term *transformational leadership* is often used interchangeably with *charismatic leadership* because they both involve creating a vision as inspiration for followers. However, they are different in a number of important ways. Charismatic leadership often occurs in times of social crisis. Followers personally identify with a charismatic leader and are inspired by them to work toward a goal. Because the leader with a charismatic style is so extraordinary, they often inspire hatred among individuals with different values. Also, while transformational style emphasizes the development, improvement, and empowerment of followers, charismatic style does not. Doing these behaviors might even serve to make the charismatic leader seem less exceptional.

More recently there has been an emphasis on leadership styles that involve ethical behavior (i.e. servant, spiritual, and authentic leadership). Servant leadership is a particularly popular style. While it originated in religious leadership, it can be applied outside of that

context as long as it involves working for equality and social justice. This style involves "serving" the follower by helping them to develop and empowering them. By serving their followers, leaders with this style hope to improve their followers' well-being. Using this style effectively results in followers who are trusting and loyal. Spiritual leadership is a style similar to servant leadership in that the leader tries to find ways to improve circumstances for followers. Spiritual leadership, though, addresses two specific needs: transcendence and fellowship. If a follower achieves transcendence, they find that their work has value that goes beyond their own personal benefits. In other words, their work achieves a greater good. A follower who has fellowship finds joyful and meaningful relationships as a result of their work. Authentic leadership is another style that has gained popularity. A leader whose behaviors are consistent with their espoused values characterizes this style. The consistency between values and behaviors shows followers that the leader has personal integrity. The transparency inherent in this style also poses a risk for leaders whose followers do not share the same values.

Poor corporate management in the twenty-first century has called for a reassessment of leadership roles. Layoffs, psychological disengagement, and economic recession are among the many consequences that can be attributed to a crisis in ethical leadership. A shift in leadership theory toward an ethical approach is crucial to eliminating uncontrolled greed, distrust, and other organizational problems. Change from the typical authoritarian style of leadership to a more benevolent one includes a focus on collaboration rather than competition. Current theories like transformational leadership have demonstrated progress in some areas of leadership research but further development into ethical sides of leadership is needed.

Benevolent leadership is defined as the process of creating a virtuous cycle of encouraging, initiating, and implementing positive change in organizations through: (1) ethical decision-making and moral actions, (2) developing spiritual awareness and creating a sense of meaning, (3) inspiring hope and fostering courage for positive action, and (4) leaving a legacy and positive impact for the larger community.

Situational leadership is based on contingency theory and was developed by Paul Hersey in the 1960s and Ken Blanchard in the 1970s and 1980s focusing on the aspect that there is no universal or best way to lead but rather that leaders have the ability to adapt to different situations. This style relies on expectations of maturity levels (M) within the group, which ultimately determines which situational leadership type (S) is used. Hersey and Blanchard each developed their own unique situational leadership model where Hersey's is the Situational Leadership Model and Blanchard's is the Situational Leadership Model II. Though both rely on the same basic principles, they decided in 1977 to work in separate organizations.

Each model describes the Four Ss of situational leadership:

- S1 Telling: high directive behavior and low supportive behavior.
- S2 Selling: high directive behavior and high supportive behavior.
- S3 Delegating: low directive behavior and high supportive behavior.
- S4 Participating: low directive behavior and low supportive behavior.

Additionally, each model describes the Four Ms of situational leadership:

- M1: Unable and insecure.
- M2: Unable but willing.

- M3: Capable but unwilling.
- M4: Very capable of and competent.

Diversity and a New Leadership Style

Contemporary researchers have been arguing for the need to reframe the leadership style debate. Eagly and Johnson (1990) conducted a meta-analysis of the research regarding gender differences in leadership styles. They examined the results of studies in three classes: organizational, laboratory, and assessment. In organizational studies, though gender stereotypes would suggest females would use a more interpersonally oriented style and males would use a more task-oriented style, they found no gender differences. However, gender stereotypes did hold across all three classes of studies when considering the democratic versus autocratic leadership styles. Females were found to lead in, and have a preference for, a more democratic style while males preferred the autocratic style.

Recent census data predict that the population of the United States, in particular, will become a majority minority nation by the year 2050. Based on these data, and more, Chin and Trimble argue for the development of a new prototype for describing leadership styles. In their book *Diversity and Leadership* (2015), they examined prior and current research and conducted face-to-face interviews with members of a number of different world cultures. Through this process Chin and Trimble developed a list of 64 characteristics and behaviors thought to be associated with effective leadership. They then created a measure that asked participants to rate the extent to which they considered these characteristics and behaviors to be necessary or unnecessary for effective leadership. Their findings suggest that the individuals who completed the survey rejected those qualities associated with the alpha-male type leadership style. Across genders and cultures, participants tended to be more in favor of characteristics and behaviors associated with a more democratic, interpersonal style. Their ongoing research appears to support the need for new research leadership paradigms to accommodate diverse multicultural leadership styles.

Character Conceptualized

Over the centuries, philosophers, theologians, psychologists, historians and managers have considered the topic of character and its relevance to leadership. *Character* represents malleable traits, cognition, affect, and behavior that reflect either the best or worst in humanity and their outcomes (ethics, happiness, well-being, and effectiveness). Character, if good, represents the willed imposition of principled habits of excellence in morality, concern for others, social interaction, spirituality, and self-respect, over the innate flaws associated with the human condition. Habits of thought inform the intellect, which uses reason to determine one's thoughts and behaviors. Habits of conduct inform the will, which exercises control over the leader's temperament, thoughts, feelings, and conduct. Good (or bad) habits of thought and conduct prompt good (or bad) behavior because habits are reinforced by the intellect and will.

Character and Leadership

Character is important to leadership because it describes what constitutes the habitual practices of leaders and followers and their effects on organizations. The personal attributes of leaders gain more importance in the way they are transmitted to followers and in the way that character mobilizes followers towards a common goal. Leaders must not only talk about good character; they must also display good character through their behaviors and encourage its development in followers. As such, leadership scholars are now agreeing that it is not enough to possess certain positive leadership characteristics; an understanding of how these characteristics operate to influence followers and organizations across situations is also required. Media accounts of ethical scandals at Enron, Madoff Investment

Securities LLC, and the US Veterans' Administration highlight failures of character in leadership. Thus, leadership character has important implications for organizations and their policies, mission, performance, and reputations.

The behavior of leaders exemplifies either what is considered to be good (virtue) or bad (vice). *Virtue* represents exemplary character and temperament, morally good and right behavior that leaders ought to do, and human excellence, all of which result in good consequences. In contrast, *vice* represents deficient character and temperament, immoral and wrong behavior that leaders ought not to display, and human degradation, all of which result in bad consequences. Virtues or vices determine the attitude leaders hold toward their community, followers, and self, and the will they exert in leading others through their behavior.

Philosophers consider the *will* to be the sum of choices, desires, motives, and responsibilities valued by an individual depending on whether virtue or vice is appreciated. The will is similar to what psychologists consider when discussing self-awareness, self-regulation, and self-motivation. Leader self-awareness, self-regulation, and self-motivation are essential to the operation of the will. They describe how leaders understand their strengths and weaknesses, make sense of events around them, adapt their behavior to situations, and persist during challenging times. This practice is an ongoing developmental process whereby they continually reflect on the unique aspects of their virtues, vices, identity, knowledge, abilities, and goals. Character-based leadership is one that can be developed through willed conduct. In developing character, leaders first need to acknowledge their ownership of the moral aspects of an environment, and then have the courage and self-efficacy to guide and direct their behavior to create a virtuous and moral environment (Hannah & Avolio, 2011). These psychological processes enable virtuous behavior to occur when principles of virtue overcome bad thoughts and feelings when leaders may be predisposed to or tempted by vices.

Classic vs. Contemporary Considerations of Character and Leadership

Leadership scholars have offered a wide variety of definitions of character by considering the nature of virtue from different perspectives. Some scholars have focused on Aristotle's cardinal virtues of justice, fortitude, prudence, and temperance from an ethical leadership perspective (Riggio, Zhu, Reina, & Maroosis, 2010). These four virtues reflect the Greek concept of "ethos," which can be translated into the word "character." Other scholars have integrated Aristotelian and Confucian virtues as courage, temperance, justice, prudence, humanity, and truthfulness (Hackett & Wang, 2012), or have identified virtues of wisdom and knowledge, courage, humanity, justice, temperance, and transcendence as foundations for authentic transformational leadership (Peterson & Seligman, 2004; Sosik, 2015; Sosik & Cameron, 2010).

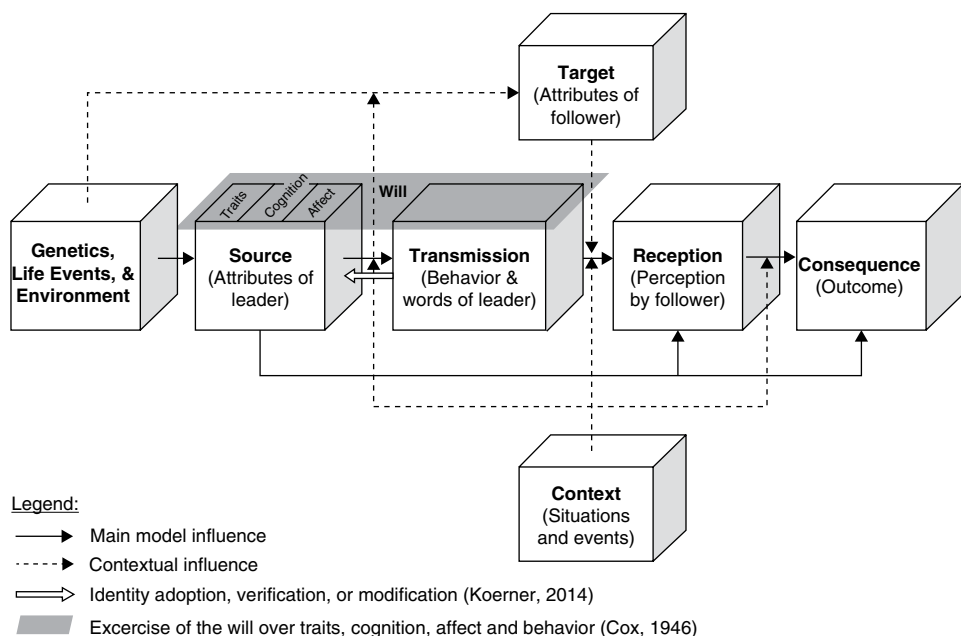
A common theme running through these perspectives are the virtuous habits of conduct superimposed on leaders' personal attributes (traits, cognition, affect) that influence how leaders behave with other individuals, and how these and prior interactions shape their self-identity over a series of life events and situations. This theme suggests that leadership character may be depicted as the process model shown in Figure 1.


Figure 1 Process model for character and leadership.

Genetics, life experiences, and the environment influence the source and target of character, namely who leaders and followers are as individuals (traits), what they think about themselves and others (cognition), and how they feel (affect). A growing stream of research focuses on *character strengths* that are defined as malleable traits and psychological processes that individuals use to display virtue, think in virtuous ways, and maintain a virtuous (positive) mental attitude. Peterson and Seligman (2004) identified 24 character strengths, which they theoretically sorted into six virtue categories (wisdom and knowledge, courage, humanity, justice, temperance, transcendence). According to Peterson and Seligman (2004), wisdom and knowledge are manifested in the strengths of creativity, curiosity, love of learning, open-mindedness, and perspective. Courage is revealed in the strengths of bravery, integrity, persistence, and vitality. Humanity is reflected in the strengths of love, kindness, and social intelligence. Justice is shown in the strengths of citizenship, fairness, and leadership. Temperance is exhibited in the strengths of self-regulation, prudence, forgiveness and mercy, and humility. Transcendence is demonstrated in the strengths of spirituality, hope, appreciation of beauty and excellence, gratitude, and humor. However, subsequent factor analytic studies have found variations in the number of these virtue categories and the sorting of the character strengths into the virtue categories. Psycho-biographical analyses have linked the development of character strengths of creativity, prudence, and hope to critical life events of leaders such as Steve Jobs, Carlos Ghosn, and Aung San Suu Kyi, respectively (Sosik, 2015). Some character strengths, such as spirituality and gratitude, are genetically predisposed, while the urban environment has been found to influence strengths such as creativity, kindness, and love.

The personal attributes (traits, cognition, affect) shown in Figure 1 represent the *sources* of leader character that are transmitted to followers through the leader's behaviors and reputation (Hannah & Avolio, 2011). Scholars have argued that character emerges and is transmitted when individuals impose their will upon their vices or negative personality traits (e.g. greed), cognitions (e.g. arrogance), affect (e.g. anger) and behaviors (e.g. laissez faire leadership). The will is a manifestation of habits of conduct that allows for the transmission of more positive sources of character, and the transformation of vices into virtues, such as over-indulgence into temperance. Willed introspection about what changes need to be made along with willed self-regulation support such character development.

As shown in Figure 1, the sources of character can have both indirect and direct effects on the outcomes or consequences of character (e.g. ethics, well-being, happiness, satisfaction, and effectiveness). The indirect effect occurs when sources of leader character are transmitted to the target (follower) via a leader's words or actions. Recent research suggests that such transmission of character validates and strengthens a moral self-identity or salient self-identity of being perceived as personifying the character strength of bravery. If a particular character strength (e.g. love of learning) is salient to the self-identity, a leader may attempt to display a behavior (e.g. intellectual stimulation) that exemplifies the strength. The direct effects of sources of character on followers and outcomes occur when leader character is transmitted through a leader's reputation. Leader categorization theory suggests that if a leader has a solid reputation for being brave and expecting courageous action from others, followers are likely to attribute bravery to the leader and act similarly in times of crisis.

The transmission of a character strength may or may not be received/perceived by the follower, depending on whether the follower appreciates the character strength, shares common values, or identifies with the leader. The transmission of character by leaders and reception of character by followers is likely to be moderated by characteristics of the follower and situation. For example, organizational or personal crises are likely to interfere with a leader's encouragement of love of learning through the display of intellectual stimulation because such crises are distractions that require attention and impede learning.

When followers perceive the leader as demonstrating a character strength that the leader wishes to exemplify, the transmission of virtuous behavior is said to be received or perceived by the follower as intended by the leader. Such perceptions of virtuous leader behavior by followers motivate action to contribute to the collective efforts to achieve the vision of the leader. Research has linked such perceptions to consequences including high performance of executives and middle managers, ethical leadership, happiness, satisfaction, and career, social, financial, physical, and community well-being (for reviews of this research, see Peterson & Seligman (2004) and Sosik (2015)).

Recent applications of research on character and leadership include assessments of character strengths manifesting virtues (VIA-IS; www.viacharacter.org), character development topics integrated in high school and university leadership courses (Sosik, 2015), and character development as the core of ethical decision-making in business programs (Crossan, Mazutis, Seijts, & Gandz, 2013). The latter application is noteworthy given its virtue-based approach to ethical decision-making whereby virtues guide relationships among leader intentions, behaviors, reflection, awareness, and judgment, given the leader's values, virtues and traits, and the situation that embeds them.

Future Considerations

Future directions in research, theory, and methodology concerning character and leadership can be drawn from the model shown in Figure 1. Regarding research, empirical studies conducted in countries influenced by Aristotelian, Confucian, and other cultures are needed to clarify the factor structure of character strengths that cluster among the virtues identified by Peterson and Seligman (2004). More field and lab studies are needed to test the proposed linkages among character sources, their transmission and reception of behaviors, and consequences proposed in Figure 1. Regarding theory, scholars are encouraged to integrate theoretical models drawn from the psychology, philosophy, sociology, theology, and management domains to identify moderating and mediating mechanisms to better explain how leader character influences follower and organizational outcomes. Figure 1 can also guide leadership research in better understanding why leaders fail due to character flaws, how authentic leadership processes operate, and when charismatic and transformational leadership can regress into their dark sides.

Regarding methodology, self-other ratings of character may overcome issues related to self-rating and common method biases. Pattern-oriented approaches to examining optimal profiles of leader character strengths are also warranted. Given that character may develop within unique dyadic leader-follower relationships embedded within teams, organizations, and societies, multilevel data analytic techniques should be used in future studies. Longitudinal studies are needed to explore how character strengths develop over time and influence the components of the model shown in Figure 1. Researchers should consider using event study methodology given the paucity of research attention placed on the situations and events that influence the source, transmission, and reception of character and leadership.

Personality and Intelligence in Employee Selection

Sami Nesnidol[1] and Scott Highhouse[2]

[1] *Ford Motor Company*
[2] *Bowling Green State University*

Intelligence and personality are two constructs commonly measured during selection procedures. The term *selection*, in the context of industrial-organizational psychology, most often refers to the selection of new employees from a pool of potential applicants. The term may also refer to selecting employees for promotion, training opportunities, and rewards.

The primary goal of selection is to accurately predict future performance in order to select quality employees who will perform well on the job. To identify these top performers, a series of preemployment assessments are often administered to applicants. Intelligence (a term often used synonymously with cognitive ability) and personality assessments are two commonly used preemployment tools that have been shown to be valid predictors of job performance. First used in large-scale selection to screen military recruits during World War I (WWI), both personality and intelligence testing were later popularized in civilian hiring contexts.

Both cognitive ability and personality scales are based on the aggregation of many items. The score from a single item is not indicative of a person's level of intelligence or a given personality trait. It is only when these scores are averaged over many items that they are able to predict future work performance consistently and accurately (in technical terms, they possess greater levels of reliability and validity).

Neither personality nor intelligence assessments are often used alone. In fact, research shows that scores on cognitive ability and personality measures are largely uncorrelated, despite both being valid predictors of performance. This means that both personality and intelligence assessments possess incremental validity over the other. In layman terms, both assessments measure different aspects of job suitability, therefore, when these assessments are combined, the resulting scores more accurately predict future performance than either assessment alone. Personality and intelligence assessments are also often combined with other selection tools such as interviews, assessment centers, and situational judgment tests, in order to gain a more comprehensive view of the applicant, which results in better predictions of future performance.

Intelligence Testing

Intelligence is a person's ability to efficiently reason, solve problems, think logically, and learn from experience. Early inconsistencies in the predictive validity of intelligence testing caused people to doubt its utility for predicting job performance. This changed with Schmidt and Hunter's (1977) landmark article demonstrating that observed differences in validity were largely due to sampling error. Currently, the most widely accepted model of cognitive ability is Carroll's (1993) three-stratum model that proposes three hierarchical levels of intelligence, the apex of which is *g*, or general mental ability (GMA), which is subdivided into broad and narrow abilities.

Cognitive ability can be assessed in a variety of ways, including interviews, assessment centers, situational judgment tests, and paper and pencil or computerized exams. Past research has shown cognitive-ability tests to be the most consistent predictor of job performance across a variety of settings and occupations. Intelligence is especially predictive of performance in technical skills as well as the acquisition of job knowledge and success in training programs. This relation between intelligence and job performance is moderated by job complexity, with this relation becoming stronger for more complex jobs. A study by Hunter and Hunter (1984) reported validity coefficients ranging from .23 for unskilled labor to .58 for high complexity jobs. Despite the strong validities associated with cognitive-ability tests, they are still not as commonly used as interviews and references checks.

A major drawback of cognitive-ability tests is that results often present large subgroup differences, with people from minority groups scoring significantly lower than Whites. Blacks are commonly thought to score around 1.00 standard deviation lower than Whites, while Hispanics have been found to score about .83 standard deviations lower than Whites. However, research has suggested that these estimates may fluctuate with the complexity of the job. The *Uniform Guidelines on Employee Selection Procedures* states that the use of selection methods that present with adverse impact (or are unfairly biased against minority groups) are permissible only when the skills being tested are required on the job, and if using alternative methods of assessment would greatly reduce the selection systems' validity (or ability to predict performance). Therefore, use of intelligence tests may place an organization at risk for legal action. Consequently, some organizations are hesitant to use intelligence tests. Other reasons for resistance to using intelligence tests include the cost of purchasing, designing, or maintaining the test, the cost of administering the test, and the potential for negative applicant reactions.

Personality

There is no wide agreement among scholars on the definition of personality; however, in general it can be thought of as a combination of internal, intangible, and enduring characteristics that affect how people interact with their environment. The popularity of personality assessment as a preemployment tool has waxed and waned. Following the proliferation of personality testing in civilian settings after WWI, their use continued to increase before declining in the 1960s and 1970s. Doubt originated from psychologists like Walter Mischel, who argued that differences in behavior were due to minor situational differences, and not

personality. This was supported by inconsistencies in the ability of personality assessments to predict behavior over similar groups and situations. These inconsistencies, however, were later rectified by personality theorists in the 1980s using the principle of aggregation, which states that, although personality assessments perform poorly when trying to predict a single event, they do accurately aid in the prediction of behavior over time. For example, the results of a personality assessment are unlikely to accurately predict whether a given employee arrives late for his shift tomorrow, but they are far more accurate at predicting whether the person will consistently arrive late.

Many different models of personality have been presented in the scientific literature, but the Five-Factor Model has emerged as the most widely accepted model. Though the names of the five factors sometimes differ, they are most commonly known as extroversion, conscientiousness, openness, agreeableness, and emotional stability. This model of personality forms the basis of most currently used preemployment personality assessments.

A combination of primary research and meta-analyses have shown personality to be related to a number of organizational behaviors, including task performance, contextual performance, job choice, performance in training, leadership, organizational citizenship, and job satisfaction. Conscientiousness has emerged as the strongest predictor of performance of the five factors with validities in the .20s for predicting training and job performance.

Another vein of research in personality assessment investigates the existence of compound variables, such as consumer orientation, which are believed to be combinations of several Big Five domains that do not necessarily covary. For example, research has suggested that integrity is a compound variable incorporating aspects of conscientiousness, agreeableness, and (low) neuroticism. Research has shown that these compound variables often result in criterion-related validates that are higher than the validities of the traits they are thought to contain, suggesting that these compound variables are, at least in some situations, better predictors of job performance than their component parts.

Personality assessments are typically presented in a Likert-style format where participants are asked to rate how strongly they agree or disagree with a list of statements meant to tap into the five factors of personality. However, personality can also be accessed through a variety of different methods including interviews, situational judgment tests, and assessment centers.

A concern with the use of personality assessments, especially those using self-report, is desirable responding, where applicants intentionally distort their responses in order to represent themselves in a favorable light. Applying for a sales position, for example, an applicant may choose to strongly agree with statements such as "I enjoy interacting with people" based on the belief that the company will want sales representatives who are more extroverted.

Previous research has examined a number of item and response formats to limit the presence of desirable responding. This has included forced-choice formats where applicants are forced to endorse only one of two statements each endorsing a different personality trait. Other methods to limit desirable responding include the use of ideal point response models, computer adaptive testing, and biographical data (i.e. biodata) about previous life experiences, and the design of subtle questions. Previous research has found that asking participants to elaborate and support their responses on biodata measures leads to a

decrease in desirable responding, although, research is mixed as to whether faking on personality assessments actually results in substantial decreases in validity.

Debate over personality assessments has also centered around their bandwidth, which involves whether or not to use broad or narrow categories based on the criterion (outcome) being measured. Meta-analytic evidence suggests that in order to maximize validity, the personality traits being measured should be theoretically relevant to the criterion including having a similar bandwidth. For example, to obtain a global assessment of how skilled someone is at interacting with customers, a large compound trait that is theoretically related to dealing with customers, such as customer service orientation, should be used. However, if a narrow outcome is being assessed, such as impression management skills when dealing with upset customers, then a more narrow trait related to the measured outcome, should be assessed.

Personality tests used in selection are only meant to assess nonclinical levels of personality, and not clinical levels of depression or other personality disorders. Tests to diagnose personality disorders should not be used for preemployment selection and should only be used in selection once a conditional offer of employment has been made for occupations where the presence of such disorders presents a large safety concern, such as a pilot or police officer.

Current Work and Future Directions

Research continues on the development and use of personality and intelligence assessments for use in selection. Personality researchers continue to investigate various item formats and ways to minimize desirable responding on personality tests. Research has also begun investigating the possibility of nonlinear relations between personality and performance. One area of current research on the assessment of intelligence is investigating how to reduce the presence of subgroup differences. Additionally, work is being done to investigate how the administration of both cognitive and personality tests in an unproctored setting influences the reliability and validity of scores. Preliminary research has been mixed, but suggests that it is possible to deliver both intelligence and personality assessments online, without supervision, when steps are taken to limit access to cheating aids on cognitive tests. Applicant reactions to online selection testing have been largely positive, but more research is needed to assess subgroup differences, especially concerning age, and the acceptance of these new testing methods by human resource and selection officials.

Sub-clinical Traits in the Workplace

Robert B. Kaiser

Kaiser Leadership Solutions

Personality psychology began with the study of disorder and dysfunction; the early pioneers' research on neuroticism, hysteria, and compulsion laid the foundation for the field. The high-water mark of this work was the 1939 publication of the *Minnesota Multiphasic Personality Inventory* (MMPI), a standardized psychometric test that became the gold standard for the objective assessment and diagnosis of psychopathology.

The MMPI was also used in workplace applications, principally personnel selection, with normal adult populations. Two trends in the latter part of the twentieth century discouraged this practice and also impacted the later study of personality disorders at work. First, the introduction of the Five Factor Model (FFM; also known as the Big Five) provided a taxonomy that greatly facilitated research, and it was focused on "normal" personality. An explosion of FFM-based research eclipsed research on abnormal personality at work. Second, the Americans with Disabilities Act, passed by the US Congress in 1990, defined psychopathology as a disability. This made it potentially unlawful to deny people employment based on scores on psychiatric screening devices.

However, two streams of workplace theory and research have focused on a middle ground between normal personality and abnormal pathology. Each concerns individual differences that are distinct from the FFM and clinical disorders, and thus may be referred to as "sub-clinical traits." Sub-clinical traits are associated with counterproductive behavior, but are not incapacitating to social functioning or debilitating to personal well-being.

Stream 1: The Dark Side of Personality

In 1990, Robert Hogan published *The Dark Side of Charisma*, a chapter that explained how some leaders use their charm and influence to advance their self-interests by manipulating and deceiving others. This dark side of their public personas, Hogan argued, is hard to identify because it is usually concealed by well-developed social skills that mask the selfish intent.

Soon after, Robert and Joyce Hogan elaborated the notion of the dark side to explain how smart, hard-working, and accomplished executives sometimes wind up getting fired. After a careful review of an emerging and largely qualitative research literature on "career derailment," the Hogans observed that the recurring themes explaining why senior managers get fired concerned interpersonal tendencies that interfered with the ability to maintain relationships, motivate employees, build a team, and make good decisions. Moreover, they noted that these troubling tendencies resembled the 11 standard personality disorders listed in the *Diagnostic and Statistical Manual of Mental Disorders IV* (DSMV). The Hogans used the DSM personality categories as a heuristic to define ordinary patterns of counter-productive tendencies, explaining that dark traits are not pathological disorders because they do not impair significant life functioning as required for a clinical diagnosis. They proposed dark-side traits as a part of normal personality that nonetheless can interfere with relationships and judgment at work.

The theoretical basis for this conception of dark-side traits can be traced to Karen Horney's influential observation that normal and pathological personalities reflect differences in degree, not differences in kind. In this view, disorders are not qualitatively distinct from normal tendencies; they are the same tendencies only in more extreme, rigid, and inflexible form, which increases the probability that they will be displayed in inappropriate social settings or to an excessive degree given the circumstances. It is this uncontrollable quality that makes disorders debilitating. Thus, dark-side traits can be viewed as extensions of normal personality traits – like those covered by the FFM dimensions of extraversion, agreeableness, conscientiousness, stability, and openness – that expand to sub-clinical levels but stop short of the extreme impairment that would classify as a clinical disorder.

The Hogans developed a psychometric test, the *Hogan Development Survey* (HDS), to measure the 11 dark-side traits as continuous dimensions of sub-clinical personality. Evidence for the construct validity of the conceptualization of the dark-side dimensions as sub-clinical traits can be found in significant, but moderate-sized, correlations with analogous DSM disorders as measured by the MMPI. Support for their conceptualization as extensions of normal personality is found in similarly significant, but moderate-sized, correlations with the dimensions of the FFM. The significant correlations indicate that the dark-side traits overlap to some degree with the MMPI disorders and the FFM dimensions, but the moderate size of the correlations suggests that they do not span identical ranges on the underlying continua.

The 11 dimensions of the dark side measured by the HDS (and their associated DSM disorders and FFM dimensions) are: excitable (borderline, low stability); cautious (avoidant, high conscientiousness); skeptical (paranoid, low agreeableness); reserved (schizoid, low extraversion); leisurely (passive-aggressive, high agreeableness); bold (narcissism, high stability); mischievous (antisocial, low conscientiousness); colorful (histrionic, high extraversion); imaginative (schizotypal, high openness); diligent (obsessive-compulsive, high conscientiousness); dutiful (dependent, high agreeableness).

The 11 dimensions empirically cluster into three higher-order factors that can be understood in terms of their self-protective and self-enhancing intent. The first five, excitable through leisurely, represent strategies used to keep others at a safe distance; the next four, bold through imaginative, represent strategies for captivating others through seduction and charm; and the last two, diligent and dutiful, represent strategies

for ingratiation by complying with the standards and expectations of others. According to Hogan, people express their dark sides when they are not being vigilant about regulating their behavior – when they are stressed, under pressure, inebriated, or simply don't care about the impression they make.

The development of a theory and measurement base for the dark side has stimulated the creation of similar personality inventories (there are at least two others) and a growing body of empirical research on these sub-clinical traits at work, largely concerning incompetent management and ineffective leadership.

Stream 2: The Dark Triad

Separate from Hogan's work on the dark side of personality, psychologists have studied the workplace effects of several narrowly defined dysfunctional dispositions originally identified in the clinical literature. However, this research has also maintained that these traits are common at sub-clinical levels in normal populations. Three traits have been particularly prominent in workplace research – narcissism, psychopathy, and Machiavellianism. Paulhus and Williams referred to them collectively as the *dark triad* because "individuals with these traits share a tendency to be callous, selfish, and malevolent in their interpersonal dealings."

Freud's psychoanalytic theory of narcissism inspired the creation of self-report questionnaires to assess a sub-clinical level of excessive self-absorption that interferes with caring about other people. The most popular of these, the Narcissistic Personality Inventory (NPI) developed by Robert Raskin and colleagues, measures two factors: a grandiose (inflated) sense of self and entitlement (expecting special treatment).

Hervey Cleckly's 1941 book, *The Mask of Sanity*, popularized the concept of psychopathy based on case studies of institutionalized men who showed no remorse for harming others. Robert Hare subsequently developed the Psychopathy Checklist (PCL), an inventory completed by a clinical psychologist on the basis of a semi-structured interview and review of official (usually criminal) records. The PCL was expressly created to make clinical diagnoses and to be used in criminal trials. Two self-report questionnaires have been developed to assess sub-clinical levels of psychopathy: the Psychopathic Personality Inventory (PPI), which measures abusive domination, impulsive antisociality, and coldheartedness, and the Self-report Psychopathy Scale III (SPS), which is based on the PCL and measures manipulation, a lack of empathy, social instability, and criminal tendencies.

Based on Niccolò Machiavelli's *The Prince*, a Renaissance treatise on how rulers should govern their subjects through duplicity and exploitation, and their study of political and religious extremist groups, Richard Christie and Florence Geis developed the construct of Machiavellianism as a form of malignant manipulation. Their self-report questionnaire, the refined Mach-IV, measures three factors: deceptive influence tactics, a cynical view of other people, and low ethical standards that justify the immoral treatment of others.

Although there are other measures of narcissism, psychopathy, and Machiavellianism, the foregoing are generally considered definitive. And although other dark traits have been studied, such as aberrant self-promotion and everyday sadism, the dark triad has been studied the most at work.

The traits in the dark triad are moderately and positively inter-correlated but also are sufficiently independent to be considered distinct. Further, they are moderately correlated with the dimensions of the FFM – most consistently, low agreeableness and low conscientiousness, reflecting their antisocial qualities. However, these correlations are small enough to indicate they are distinct from normal personality as defined by the FFM.

Findings

There is a cumulative body of empirical research on the effects of the dark side of personality and the dark triad in the workplace. The two streams of research have proceeded in relative isolation from one another, so there is little research on how the two systems relate or compare in predicting work processes and outcomes. Further, organizational research in the two traditions has taken somewhat different paths: studies of the dark side have focused almost exclusively on leadership and managerial performance, whereas studies of the three dark triad traits have examined a broader population that also includes employees.

There is considerable construct validity evidence for each set of sub-clinical traits. Machiavellianism is associated with lying and seeking revenge. Narcissism is associated with inflated self-evaluations and with hostility and aggression – especially under conditions of ego threat, and psychopathy is associated with mistreatment of others, including criminal mistreatment. The 11 dimensions of the dark side of personality similarly correlate in consistent ways with observer ratings of conceptually related work behaviors.

Meta-analytic findings confirm the robustness of the effects of sub-clinical personality at work. One study of the results from 245 independent samples found that all three of the traits in the dark triad were related to counterproductive work behavior and that Machiavellianism and psychopathy were related to lower job performance. Together, the dark triad traits explained a moderate amount of variance in counter-productivity, but less variance in job performance. A separate meta-analysis of 256 studies using the HDS found that all 11 dimensions of the dark side of personality were negatively related to at least one of seven dimensions of managerial performance (e.g. Leading others, Dependability, Adaptability, Interpersonal skill, Problem solving).

Complexities

Although the dark side and dark triad traits are generally negatively related to desirable processes and outcomes in the workplace, they are sometimes found to relate differently to performance. Some studies have reported that low levels of dark-side traits are unrelated to performance, but scores ranging from average to high are increasingly associated with lower performance. Other studies have shown that some dark traits are actually positively associated with some work outcomes.

For instance, a meta-analysis of narcissism found it to have a positive, linear relationship with leadership emergence (being nominated or hired for a leadership role) but an inverted, U-shaped curvilinear relationship with leadership effectiveness (performing well in a leadership role). Evidently there is an optimal level of positive self-regard near the middle of

the distribution that is useful in inspiring confidence and influencing others, but beyond that point higher levels of narcissism become increasingly detrimental to effective leadership. However, the positive relationship with leadership emergence indicates that higher levels of narcissism are associated with greater advancement into leadership roles. These differential effects suggest that those who score very high on narcissism may be able to charm and dazzle their way into leadership jobs, but once in higher office their self-absorption prevents them from leading effectively. In other words, some seemingly charismatic leaders may be hired for the very same factors that undermine their leadership and ultimately get them fired.

More research is needed to untangle the complex effects of sub-clinical traits in the workplace. It appears that for some outcomes, these dark, self-interested tendencies have negative effects, but for others they may be beneficial. It will be necessary to distinguish workplace outcomes that benefit the individual (e.g. promotion, leadership emergence) from those that benefit the organization (e.g. effect on coworkers, job performance, leadership effectiveness) over time and to consider the possibility that there is an optimal level of sub-clinical traits, where both extreme high and extreme low scores have undesirable consequences.

Bullying and Personality

Jeffrey S. Mintert and Alisia G.T.T. Tran

Arizona State University

Bullying is an intentional aggressive behavior that is repeated over time and marked by an imbalance of power between involved parties, thus creating a bully and bullying victim. Bullying behaviors are most common among youth, but can also occur between adults, for instance, in the workplace. Bullies may engage in proactive or reactive aggressive behaviors. *Proactive aggression* occurs without provocation, whereas *reactive aggression* is in response to a trigger, such as being picked on. There appear to be a wide range of personality factors, such as neuroticism, hostile attribution of intent, and narcissism, that contribute to an individual's propensity to bully others, but researchers have not been able to identify a single cohesive profile.

The Big Five

Perhaps the most commonly discussed aspects of personality are the Big Five personality traits (e.g. openness, conscientiousness, extraversion, agreeableness, neuroticism). Limited research has examined the role of these traits in bullying. A study examining cyber-bullying (bullying behaviors conducted using technology) found that cyberbullies scored lower on conscientiousness and higher on neuroticism as compared to their peers (Kokkinos, Antoniadou, Dalara, Koufogazou, & Papatzki, 2013). Bullies also scored higher on extraversion than their peers, which may reflect an ability to assert themselves socially (Tani, Greeman, Schneider, & Fregoso, 2003). Unsurprisingly, bullies scored lower on agreeableness than peers who intervened and tried to help the victim (Tani et al., 2003). Within the extant literature to date, it appears that only openness to experience is unrelated to bullying behaviors.

The Dark Triad

Researchers have identified a collection of personality traits that many perpetrators of bullying endorse known as the *dark triad*. The dark triad consists of Machiavellianism, sub-clinical psychopathy, and sub-clinical narcissism, which are associated with increased aggression that may be contributory to bullying (Paulhus & Williams, 2002). Specifically, the dark triad has been linked with increased physical aggression (narcissism and psychopathy) and relational aggression, or aggression that affects one's social relationships (Machiavellianism; Kerig & Sink, 2010).

Among the three constructs, psychopathy appears to have the strongest link with bullying behaviors followed by Machiavellianism and, lastly, narcissism (Baughman, Dearing, Giammarco, & Vernon, 2012). Youth with higher levels of psychopathic traits (e.g. callousness, lack of empathy) displayed more aggression (e.g. administering a potentially harmful sound to a confederate posing as a victim) than youth in the low psychopathy group. However, there was no difference when the youth with higher levels of psychopathic traits were aware of the victim's distress (e.g. comments made to the participant by the confederate about being worried the noises were too loud), suggesting that awareness of the victim's distress level might inhibit aggressive behavior (Van Baardewijk, Stegge, Bushman, & Vermeiren, 2009). The researchers suggested that interventions designed to increase empathy might help to mitigate the level of aggression displayed by youth who exhibit psychopathic traits (Van Baardewijk et al., 2009). Callous-unemotional traits (i.e. disregard for others, decreased affective response) are also understood as major components of psychopathy and have been directly linked to increased bullying behavior in adolescents (Ciucci & Baroncelli, 2014).

Machiavellianism has been most commonly understood as a cold and manipulative style of interacting with others (Paulhus & Williams, 2002). Machiavellianism is related to adolescent bullying behavior, particularly indirect forms of bullying behavior, such as spreading rumors. Youth who bully others scored higher on Machiavellianism as compared to their uninvolved peers. Bullies with higher scores on Machiavellianism are thought of as "adaptive bullies" in that they are generally liked by peers even though they exploit their victims (Wei & Chen, 2011).

Narcissism is a multidimensional construct that consists of feelings of grandiosity and superiority, a sense of entitlement, exploitation of others for personal gain, a lack of empathy for others, and an excessive need for admiration from others (Martinez, Zeichner, Reidy, & Miller, 2008). Past research has linked narcissism with aggressive behaviors in adult samples and among youth. A longitudinal study conducted in the Netherlands found that narcissistic boys were more likely than their peers to display both elevated direct and indirect bullying behaviors (Reijntjes et al., 2015). Narcissistic boys who engaged in bullying concurrently scored high on social dominance, or the degree to which an individual prefers social hierarchies that result in the domination of lower-status groups (Pratto, Sidanius, Stallworth, & Malle, 1994). Bullies expressed a higher desire to be socially dominant, which suggests that bullies might score higher on measures of social dominance orientation, a personality trait that reflects an individual's preference for group-based discrimination (SDO; Olthof, Goossens, Vermande, Aleva, & van der Meulen, 2011; Pratto et al., 1994). Among adults, higher scores on SDO were positively correlated with bullying behaviors in the workplace (Parkins, Fishbein, & Ritchey, 2006).

Hostile Attribution of Intent

A chronic hostile attribution of intent is a dispositional tendency to perceive hostile intent from ambiguous actions by others (Dodge, 2006). For example, an individual who exhibits a hostile attribution of intent might interpret a neutral interaction with another as being intentionally hostile. Aggressive youth are more likely to have a hostile attribution of intent as compared to unaggressive peers (De Castro, Veerman, Koops, Bosch, & Monshouwer, 2002). Both bullies and victims scored higher on a measure of hostile attribution of intent compared to peers who were not victims or bullies. The higher levels of hostile attribution of intent displayed by bullies and victims may result in increased aggression. Higher levels of hostile attributions were negatively associated with traditional aggression (e.g. physical harm), which supports the notion that physical bullying can be a form of proactive aggression as youth who exhibit traditional aggressive behaviors do so regardless of the intent of the victim (Pornari & Wood, 2010). Additionally, hostile attributions of intent were positively related to victimization, suggesting that victims of bullying might sometimes react aggressively (reactive aggression) to provocation (Pornari & Wood, 2010).

Social Skills in the Workplace

Ronald E. Riggio

Kravis Leadership Institute, Claremont McKenna College

Social skills in the workplace refer to the broad range of skills used in communicating with others and in creating and maintaining good interpersonal relationships at work. Although many scholars and professionals recognize the importance of good social skills in the workplace, there is surprisingly little research on the topic. One reason for the paucity of research is the lack of an agreed-upon framework or theory for conceptualizing and measuring workers' "social skills." Instead, scholars have focused on broad constructs such as social intelligence, emotional intelligence, and nonverbal communication skills, that are actually composites of individual social and interpersonal skills. Other researchers have studied only one or a few individual social skills, such as listening ability, assertiveness, empathy, and others. The latter approach tells us about the effectiveness of the particular skill(s), but does not answer questions about broader, "clusters" of social skill.

One model of very basic communication skills suggests that there are three types of skills: skills in expressing oneself; skills in receiving others' communications; and skills in regulating and controlling the flow of communication. These three skills operate in two domains: verbal/social communication, consisting of written and spoken language and knowledge of social rules and conventions; and, nonverbal communication that involves the expression of emotions, affect, interest, and displays of dominance-submissiveness (Riggio, 1986). A self-report measure, the Social Skills Inventory, assesses these six basic social skills (Riggio & Carney, 2003).

Other scholars have attempted to create taxonomies for the various social, or interpersonal, skills that are used in the workplace to develop good working relationships with colleagues and team members, and to facilitate communication between supervisors and subordinates. These taxonomies range from two to six or more categories with dozens of specific types of social skills in these categories (Beenen & Pichler, 2016).

One such taxonomy divides interpersonal skills into two categories: communication skills and relationship-building skills. Communication skills include *active listening, oral communication, written communication, assertive communication* and *nonverbal communication*. Relationship-building skills include *cooperation and coordination, trust, intercultural sensitivity,*

service orientation, self-presentation, social influence, and *conflict resolution and negotiation* (Klein, DeRouin, & Salas, 2006).

An important issue concerns the measurement of social skills in the workplace. One approach is to take an individual differences perspective – attempting to assess people's possession of these social skills and assuming that these are used in the workplace to build and maintain good relationships with coworkers and others. Individual differences in social skills are often measured through self-report or ratings by others who know, or who have worked with, the individual. A second approach is to measure the behavioral display of social skills at work – giving people evaluations or scores on how well they demonstrate each skill in their workplace interactions. The individual differences approach is useful in determining persons who have potential to use their workplace social skills effectively, while the latter approach allows assessment of whether the individual actually displays effective social skills at work.

Another way to understand social skills is to view them as a manifestation of different forms of intelligence – in particular, emotional and social intelligences. Emotional intelligence (EI) is the ability to identify, express, understand emotions, use emotions in thinking and problem solving, and ability to regulate positive emotions, both in oneself and in others (Matthews, Zeidner, & Roberts, 2002). Emotional intelligence has been conceptualized both as a set of abilities or skills – in what is called the *abilities model* – or as a combination of abilities and personality traits such as empathy and sensitivity, what is called the *mixed model* (Mayer, Salovey, & Caruso, 2000). The abilities model is most aligned with social skills in the workplace. The measurement of the abilities model of EI uses a performance-based measure with right and wrong answers asking test-takers to identify emotions accurately, or demonstrate knowledge about emotional situations. In that way, it is very much like a regular intelligence test. EI measures based on the mixed model are more similar to self-report personality tests. Both measurement approaches have particular strengths and drawbacks and the construct of emotional intelligence remains somewhat controversial in academic circles, with critics arguing that EI does not constitute a true "intelligence."

Emotional intelligence became a very well known construct as popular books were written extolling the importance of emotional intelligence in everyday life and in success in the workplace (Goleman, 1995, 1998). Practitioners were drawn to emotional intelligence because it was a way to more easily focus on the complex nature of social skills that are used to maintain social relationships, particularly at work. For scholars, however, emotional intelligence is a controversial topic because of the competing models of emotional intelligence (i.e. *abilities* vs. *mixed* models) and the difficulty in measuring emotional intelligence. Enthusiasm by practitioners and trainers over this new construct, however, has led to the creation of programs to develop emotional intelligence, and these have became quite common in employee development and training programs.

While emotional intelligence deals with social skills related to the emotional, or "feeling" aspects of relationships and workplace interactions, the construct of social intelligence attempts to capture the more "thinking" aspects of workplace interactions and relationships. Marlowe (1986) defines social intelligence as "the ability to understand the feelings, thoughts, and behaviors of persons, including oneself, in interpersonal situations and to act appropriately on that understanding" (p. 52).

One model of social intelligence suggests that its two main components are *social perceptiveness* and *behavioral flexibility* (Zaccaro, Gilbert, Thor, & Mumford, 1991). Social perceptiveness is defined as "the capacity to be particularly aware of and sensitive to needs, goals, demands, and problems at multiple levels, including individual members, relations among organizational subsystems, and interactions" (Zaccaro, et al., 1991, p.321). Behavioral flexibility is defined as "the ability and willingness to respond in significantly different ways to correspondingly different situational requirements" (p. 322). This would mean that socially intelligent persons would adapt easily to the various workplace situations they might find themselves in.

Besides being socially perceptive and behaviorally flexible, there may be other social skills involved in social intelligence, including knowledge of social norms and conventions, ability to articulate and speak clearly, skills in persuasion, effective and active listening, and the list goes on. The Riggio (1986) model discussed earlier suggests that basic social intelligence can be measured through the self-report of three social skills: *social expressiveness*, or ability to speak and engage others in conversation; *social sensitivity*, which is ability to understand and decode verbal communications, a knowledge of social norms, and ability to "decode" social situations, and; *social control*, which consists of sophisticated social role-playing skill. Another term used to describe the social skills that comprise social intelligence is *social competence*.

Another model that incorporates both emotional and social intelligences, but does not explicitly use the term "intelligence" focuses on emotional and social *competencies*. This is more closely aligned with the notion of these social and emotional abilities representing different forms of social skills. Moreover, this model has been applied particularly to the workplace, and especially to managers/leaders in organizations (Boyatzis, Gaskin, & Wei, 2015). According to this model, emotional competencies are very similar to the elements of emotional intelligence, including emotional self-awareness, emotional self-control, but also includes *achievement orientation* and having a *positive outlook*. Social competencies include social awareness (knowledge of how to handle relationships), influence and conflict management, and teamwork. There has been much less research on social intelligence and social competencies in comparison to emotional intelligence, primarily because there are few accepted and widely used measures of social intelligence.

The Development of Workplace Social Skills

As noted, the development of the constructs of emotional intelligence and social intelligence, and the popularity of viewing skills/competencies as forms of intelligence, have spurred the creation of programs to train and develop both emotional intelligence and social intelligence. Yet, these training programs vary greatly in terms of both the conceptualization of the components of emotional and social intelligence and the means for developing the individual components. Moreover, there is little research on the efficacy of these types of training programs.

An additional approach to workplace social skill training programs is to focus on specific workplace skills. Most of these programs focus on certain techniques (such as active listening or conflict resolution strategies) designed to give people the social skill tools to deal

with others in the workplace and maintain good interpersonal relationships. Training programs may also target public speaking, presentational skills, and networking skills. These types of programs are a common part of employee training in many organizations.

There is a general belief that social skills are particularly important for workplace managers and leaders. As a result, the lion's share of training resources is devoted to managerial/leadership training and there are numerous programs offered as management or leadership development that focus on developing interpersonal and social skills. A recent review of some of the better-known programs suggested "best practices" for developing leader interpersonal and social skills (Murphy, Putter, & Johnson, 2014). These include classroom-based training, the use of feedback by coaches and mentors, and using on-the-job experiences for developing leader workplace social and interpersonal skills.

Classroom-based training for social skills is cost effective because it can be done in large groups, but "hands-on," experiential learning exercises (e.g. role-playing, in-class team projects) tend to enhance the lecture format learning. Practice/homework outside of the classroom is also important.

Another technique for social skill development involves the use of coaches and/or mentors who can model effective employment of social and interpersonal skills, provide feedback, and note areas of deficiency or strength. Coaches/mentors may actually "shadow" their trainees in order to observe their use of social skills in the workplace – using this information to make suggestions for improving workplace social skills. This is more costly than classroom-based training, but offers development opportunities tailored particularly to the individual.

A third type of social skill development programs uses challenging workplace assignments that require workers to utilize and hone their social and interpersonal skills. This may include rotating job assignments, giving employees demanding leadership responsibilities, or requiring them to make presentations. Team projects can also be used to help develop team social skills and skills in conflict management and negotiation. Feedback about team members' performance and social skill strengths and deficiencies are noted after the project is completed.

In conclusion, workplace social skills are critical to the effective functioning of organizations, and they are a major part of an important skill set for employees and managers/leaders. The complexity of workplace social skills has made it a difficult topic to research, and attempts have been made (and continue to be made) to try to develop an agreed-upon framework, or model, for better understanding these important variables. The importance of workplace social skills has no doubt led to the large amount of resources that are devoted to improving employee social and interpersonal skills.

Personality and Workplace Deviance

Peter D. Harms[1] and Seth M. Spain[2]

[1] *University of Alabama*
[2] *Binghamton University*

Counterproductive work behaviors (CWBs; also called workplace deviance) are intentional behaviors that harm the organization or its members that are contrary to the organization's legitimate interests. CWBs include a wide variety of acts, such as theft, sabotage, destruction of property, substance abuse at work, absenteeism, and intentionally unsafe behavior – but not accidents (Gruys & Sackett, 2003). Personality traits influence all aspects of the processes that lead to counterproductive behaviors including selecting environments that allow opportunities for CWBs, interpreting the intentions and actions of others (e.g. hostility), and the capacity for controlling one's thoughts, emotions, and behaviors.

Traits

The Big Five personality traits consist of five major dimensions along which we generally differentiate individuals in terms of their behavioral tendencies: extraversion, emotional stability, agreeableness, conscientiousness, and openness to experience. Lower levels of conscientiousness, agreeableness, and emotional stability are associated with higher levels of CWBs (Berry, Ones, & Sackett, 2007). These relationships tend to be magnified when individuals have greater autonomy on the job (Kaiser & Hogan, 2006). Different types of CWBs have differential relationships with personality traits. For example, CWBs targeting other individuals are more related to lower levels of agreeableness, whereas CWBs targeting the organization are more related to lower levels of conscientiousness. These relationships are not necessarily linear. For both emotional stability and conscientiousness there is evidence that extremely high scores can also be associated with workplace deviance because the individual may lack empathy or be overly perfectionistic (Le et al., 2011). Higher levels conscientiousness and lower levels of negative affect also tend to mitigate the negative effects of job stress on workplace deviance (Bowling & Eschleman, 2010).

The relationships observed between personality traits and CWBs can also be impacted by methodological factors. For example, the effects of personality on CWBs and withdrawal behaviors can be grossly underestimated or even have their direction reversed when poorly abbreviated measures are used in lieu of more robust measures (Credé, Harms, Nierhorster, & Gaye-Valentine, 2012).

These five dimensions do not subsume the other domains of personality (e.g. motives, abilities, values). Next, we review a number of other models and personality characteristics that also predict workplace deviance.

Attachment Styles

Attachment theory argues that all individuals are born with the desire to seek proximity to others in times of distress to enhance their survival prospects (Harms, 2011). A history of successfully attaining the aid of attachment figures (initially parents, but later romantic partners and managers) leads individuals to develop a sense of security and a willingness to trust others. Repeated failures to attain help when it is sought results in the individual internalizing the belief that either extreme emotional outbursts are needed in order to have one's needs recognized and met (an anxious style) or that there is little point to developing close relationships with others (an avoidant style). Individuals with insecure or dysfunctional attachment styles are more prone to lash out at their coworkers and organizations when their attachment needs were not met.

Dark Personality

Dark personality concerns traits that can lead individuals to derail in their careers or daily lives. These traits are more likely to be activated in periods of stress when the individual is unable to hold back their dark impulses by adhering to social norms and expectations (Hogan & Hogan, 2001). These are characteristics associated with a desire to harm others. There is an increasing body of research linking dark personality constructs such as narcissism, Machiavellianism, psychopathy, and aggression to workplace deviance (Spain, Harms, & LeBreton, 2014). It should be noted, however, that recent research has found that dark traits are not necessarily negative and can be associated with positive training and performance outcomes (Harms, Spain, & Hannah, 2011).

Cognitive Ability

Workplace deviance was positively associated with cognitive ability in a large, longitudinal community sample (Roberts, Harms, Caspi, & Moffitt, 2007). More recent work has found similar positive effects, but some have also found negative relationships between these variables (Dilchert, Ones, Davis, & Rostow, 2007). This apparent contrast can be partially explained by study design. Within specific occupations, cognitive ability is associated with lower levels of workplace deviance. However, across occupations, it can be positively associated with workplace deviance because cognitive ability is also positively associated with attaining jobs with more autonomy and more opportunities to engage unethical behavior (e.g. coming late, yelling at other employees, access to money and secure areas).

Other Forms of Deviance

Destructive Leadership

Destructive leadership is a special form of workplace deviance that exists within the role of a leader (Krasikova, Green, & LeBreton, 2013). As could be expected, destructive leaders have been shown to negatively influence the health and productivity of their subordinates. Although there has been some work showing that dark personality traits such as Machiavellianism are associated with higher levels of destructive leadership, most research on personality has investigated what types of people are typically victimized by these individuals. For example, individuals who report higher levels of abusive supervision tend to be lower on agreeableness and conscientiousness and higher on neuroticism. One reason why individuals who fit this profile may be more likely to experience abuse or bullying is because this profile is associated both with underperformance, and a tendency to evoke more negative reactions from others as a result of their chronic complaining and resisting the demands of others (Wang, Harms, & Mackey, 2015).

Of the dark personality traits, narcissism has been the most thoroughly examined with regards to leadership outcomes. The relationship between narcissism and leadership is nonlinear. Extremely low levels of narcissism can be associated with ineffective leadership, but very high levels of narcissism can also result in toxic forms of leadership.

Job Withdrawal

Withdrawal behaviors (e.g. coming in late, working slowly on purpose, faking sick to take time off) are a special form of workplace deviance. Meta-analytic evidence suggests that CWBs and withdrawal behaviors share many of the same antecedents (Zimmerman, 2009). Higher levels of turnover intentions are associated with lower levels of conscientiousness, emotional stability, extraversion, and agreeableness. Actual turnover is related to lower levels of conscientiousness, emotional stability, and agreeableness. Outside of the Big Five framework, withdrawal behaviors have also been shown to be related to higher levels of anxious attachment (Harms, 2011).

Accidents and Safety

Work accidents and injuries have been linked with higher levels of neuroticism and lower levels of agreeableness as well as low levels of conscientiousness and higher levels of risk-taking (Christian, Bradley, Wallace, & Burke, 2009). Although workplace accidents themselves are not considered CWBs, the effects of some personality traits on these outcomes was shown to be mediated through safety behaviors that suggests that potentially there was willful disregard for safety procedures.

Effects of Workplace Deviance on Personality

Although most research linking personality to workplace outcomes examines personality as a causal agent, there is an emerging literature addressing how workplace experiences change personality. For instance, individuals who commit more CWBs are not only

lower on conscientiousness and emotional stability, but that they also fail to experience positive growth on these characteristics as they age; over time they increasingly fall behind their peers who are increasing in conscientiousness and emotional stability (Roberts, Walton, Bogg, & Caspi, 2006). This developmental pattern, where traits relevant to a particular behavioral pattern are, in turn, changed by those behaviors is known as the correspensive effect.

Future Directions

For both workplace deviance and personality, there are recent developments expanding what constructs are being investigated in research. For example, some behaviors may not be immediately recognized as forms of workplace deviance, but can nonetheless have negative long-term consequences for organizations. For example, silence or refraining from calling attention to illegal or immoral practices or unethical pro-organizational behaviors whereby individuals commit deviant acts with the goal of helping their organization. To date, there has been no research linking these outcomes to personality characteristics.

For personality, much of our understanding of personality processes has been brought under scrutiny by the rise of functionalist accounts of personality (Wood, Gardner, & Harms, 2015). Functionalist accounts insist on determining *why* behaviors happen rather than *what* typically happens (e.g. trait theory). Because of this, these models can potentially lead to more precise selection tools and interventions to prevent incidents of workplace deviance. Thus far, this approach has not been examined in real-world settings.

Concluding Statement

Personality characteristics and other individual differences such as cognitive abilities have substantial relationships with workplace behavior. Because of their discretionary nature, deviant work behaviors are particularly strongly related to individual differences. While the existence of these relationships is clear, the reason for their existence needs further exploration. In particular, mere documentation of these relationships does not provide any levers for organizational interventions to mitigate deviance and its consequences.

Integrity Testing and Counterproductive Work Behavior

Casey Giordano[1], Deniz S. Ones[1], and Chockalingam Viswesvaran[2]

[1] *University of Minnesota*
[2] *Florida International University*

Integrity tests – psychological measures designed to identify and provide an evaluation of individuals that are more likely to engage in counterproductive work behaviors (CWB) – have been an integral tool used in employee selection for over 60 years (Ones, Viswesvaran, & Schmidt, 2012). CWB affect organizations in a number of ways, producing financial repercussions, influencing psychological well being of their employees, and altering their social impact. Economic costs associated with excessive absenteeism, theft, sexual harassment, and workplace violence are quite severe and place an unnecessary strain on the organization. Putting aside financial losses, organizations are well aware of the toxic psychological impact CWB have on their employees. Depression, anxiety, lowered job satisfaction, and even fears of coming into work have all been linked to CWB experienced by employees and are cause for concern to *any* organization. Similar to crime, the societal impact of CWB is detrimental and an abundance of CWB within an organization could tarnish its reputation with the general public.

CWB are defined as volitional behaviors that detract from the well-being and goals of an organization or its stakeholders (Ones & Dilchert, 2013). CWB have been defined and measured in a multitude of forms. Common synonyms of broad level CWB include antisocial behaviors, workplace deviance, organizational-retaliation behaviors, insidious workplace behaviors, and still others. Narrower and more restricted measures and constructs have burgeoned since the early 2000s and include labels such as abusive supervision, social undermining, cyber-loafing, among others.

Structure of CWB

Until the mid-1990s, many of these deviant behaviors were studied in isolation from each other, which resulted in disparaging conclusions, such as low base-rates of occurrence and poor predictability. Although some researchers have acknowledged and documented many

manifestations of CWB (e.g. property deviance, production deviance, theft, and broad CWB (Ones, Viswesvaran, & Schmidt, 1993), systematic creation and testing of CWB taxonomies did not occur until 1995.

Robinson and Bennett (1995) proposed a taxonomy linking various CWB forms under one umbrella. In their taxonomy, targets constitute a major distinguishing feature between different CWB forms; namely, CWB was partitioned into deviant acts committed against people and deviant acts against the organization. Following their taxonomy, Bennett and Robinson developed a scale that measures interpersonally and organizationally directed deviance (Bennett & Robinson, 2000). Subsequent researchers have proposed a greater number of more specific CWB dimensions. For example, Spector and colleagues (Spector et al., 2006) parsed the construct into five facets: abuse, production deviance, withdrawal, theft, and sabotage. Essentially, they relabeled interpersonal deviance as abuse and splintered organizational deviance into the remaining four facets. Despite the difference in factor structures, researchers unambiguously agree that these behaviors are all positively correlated; people that exhibit one behavior are likely to also exhibit others. In other words, there is a general factor of CWB (Stanek, Ones, & McGue, 2017).

Expanding beyond the realm of work, CWB are highly related to other forms of deviance across all aspects of life. Research has shown that a broad general factor, named common counterproductivity, is strongly related to deviance in school (high school and college), work, nonwork interactions (e.g. traffic violations, fights at a bar, failing to repay debts, etc.), and even adult alcohol/drug use (Stanek et al., 2017). Nonwork counterproductivity has recently been branded off-duty deviance.

Taxonomies like Bennett and Robinson's and Spector and colleagues' have helped bridge the gap between the separate streams of CWB research. However, one group of behaviors is not found under these prominent conceptualizations of CWB. Drug and alcohol abuse have been largely omitted from the various CWB taxonomies. These behaviors have lower relationships with other deviant behaviors and are the least prominent markers of the general CWB factor.

Antecedents of CWB

In an effort to reduce the occurrence of these behaviors, psychologists have studied their correlates using both situational and individual difference perspectives (Mercado, Dilchert, Giordano, & Ones (2018). The former is useful in designing interventions and environments where CWB can be controlled, whereas the latter is useful for identifying the individuals with reduced propensities to engage in CWB, regardless of the situational pulls and pushes. Among individual differences variables, personality variables are particularly potent predictors (Berry, Ones, & Sackett, 2007). Among the Big Five, conscientiousness, agreeableness, and emotional stability have the largest relationships with the various forms of CWB. Of the three, conscientiousness has the largest and most robust correlation. Interestingly, these three factors of personality comprise the meta-trait stability/socialization, also referred to as factor alpha, which has been described as a person's propensity to get along with others.

Other notable individual difference measures related to CWB are negative affectivity and cognitive ability. Negative affectivity, a trait at the core of neuroticism, has been studied in relation to CWB with moderate correlations. The predictive usefulness of cognitive ability for CWB has received increased attention in recent years. When multidimensional, multi-item scales of objective CWB constitute the criteria, cognitive ability appears to be a useful predictor (Dilchert, Ones, Davis, Rostow, 2007).

Integrity Tests

Integrity tests – sometimes referred to as honesty tests – assess individual differences traits related to trustworthiness of individuals. As many have discussed the theoretical rational behind these measures (cf. Ones & Viswesvaran, 2001), only a brief historical account is provided. Prior to the 1990s, several integrity tests were created and successfully implemented in organizations. However, their use skyrocketed with the passage of the Employee Polygraph Protection Act of 1988. Polygraph evaluations were subsequently outlawed in organizations for employee selection purposes, which led many professionals to seriously consider alternative sources to distinguish honest from dishonest job applicants. Currently integrity tests are administered to countless organizations across the globe and for a wide variety of jobs. Two types of integrity tests exist, overt tests and personality-based tests. Overt measures of integrity, as the name implies, explicitly ask test-takers about their attitudes of, and in a few cases include items about past incidences of, CWB. On the other hand, personality-based assessments are subtle and covert in nature. They rely on personality type items that successfully assess traits such as trustworthiness.

Construct Validity for Integrity Tests

With the abundance of integrity tests developed in the wake of the Polygraph Act, critics began to question whether the multitude of tests were indeed measuring similar constructs. Comprehensive meta-analyses quelled these arguments by showing strong relationships among the various personality-based tests and strong relationships among overt integrity tests (Ones et al., 1993). Most importantly, there exists a rather strong tie between between the two types of integrity tests. While a perfect overlap does not exist, there is compelling evidence supporting the idea that all integrity tests, whether overt or personality-based, measure the same underlying construct.

Psychologists first believed that integrity tests were essentially assessing the personality trait of conscientiousness. In search of empirical evidence, Ones (1993) turned her attention to meta-analysis. As theorized, she found that integrity tests largely tap into the domain of conscientiousness. However, the personality factors of agreeableness and emotional stability had meaningful relationships with integrity tests. Combined, conscientiousness, agreeableness, and emotional stability comprise factor alpha, a meta-trait commonly regarded as an indicator of a person's stability.

Criterion-Related Validity of Integrity Tests

Integrity tests were originally developed to assess important criteria for organizations. As a result, the bulk of the literature is dedicated to examining the relationships between integrity tests and criteria such as CWB and job performance. Regarding the relationship with CWB, integrity tests have had great success at pin pointing individuals with a greater proclivity to commit these deviant acts. Owing to its relations with factor alpha, integrity tests are among the very best noncognitive predictors of job performance. When used in conjunction with that of cognitive measures, integrity tests provide more incremental validity than any other type of measure (e.g. interviews, biodata, situational judgment tests, etc.).

Two particular methodological approaches have been utilized to assess the magnitude of the relationship between integrity tests and the the various criteria, using predictive and concurrent validity study designs. Across thousands of job applicants, analyses have shown strong support in the predictive power of integrity tests for criteria such as job performance and CWB. It is important to note that objective measures of CWB have notably lower validities than general self- and other-reported CWB. Objective measures of CWB, such as theft and property deviance, are typically more severe in nature and thus have low base-rates of occurrence making it difficult to detect.

More recent analyses have examined the relationship between integrity tests and a host of other criteria. Analyses repeatedly illustrate marked validities with criteria such as training performance, property damage, accidents on the job, objective measures of job performance, and still others. Objectively measured job performance studies have slightly weaker links to integrity tests but this attenuation is due, in part, to the behavior versus outcome dilemma. Behaviors (e.g. supervisor-rated job performance) reflect acts under the control of an individual whereas outcomes (e.g. objective records) introduce unwanted environmental constraints and biases that mask the true correlation. Figure 1 depicts the operational validities of integrity tests for a variety of criteria, based on meta-analytic results.
Figure 1   Integrity test-work behavior relationships from meta-analyses.

Unless otherwise indicated, the depicted validity coefficients reflect a combination of overt and personality-based assessments.

Even though integrity tests show substantial overlap with measures of personality, these inventories show greater predictive power for job performance, training performance, and general CWB than optimally weighted Big Five composite scores. In fact, integrity tests are the best predictor of CWB and among the best predictors for job performance in the field of Industrial and Organizational psychology. Many of the behaviors predicted by integrity tests are vitally important to all organizations across the globe. By implementing integrity tests, organizations are better able to abstain from hiring potentially deviant applicants all while increasing the chances of selecting the highest performing applicants. This conclusion generalizes across substantially different jobs, industries, and holds even in substantially different environments. Organizations would do well to continue the use of integrity tests, whether they use personality-based or overt inventories.

Learning Styles / Fixed vs. Growth Mindset

Mark Hallahan

College of the Holy Cross

Mindsets

To what extent are basic human attributes and abilities changeable? People differ in what they believe regarding this enduring question about human nature and those beliefs influence their own goals, behaviors, and reactions to life events in ways that are consequential and surprisingly far-reaching. The concept of mindsets, developed by psychologist Carol Dweck, involves implicit beliefs about the degree to which people can change. There are two contrasting sets of beliefs. A fixed mindset, or entity theory, describes a view that human characteristics are essentially set and unchanging, whereas a growth mindset, or incremental theory, describes a view that these characteristics can change and develop over time based on a person's effort and experiences. Research on mindsets, which initially focused on intelligence but has since expanded to cover implicit beliefs about many other attributes, has demonstrated crucial differences between people who have a fixed versus growth mindset.

Mindsets Influence Goals and Learning Styles

In Dweck's theoretical framework (Dweck & Leggett, 1988), implicit beliefs about intelligence, goals, and learning styles are conceptually interrelated. In situations that require the application of their intellect, people's beliefs about the nature of intelligence will influence their goal and, in turn, lead them to behave in a manner to best attain that goal. Believing that one's level of intelligence is unchangeable will result in a performance goal, where the objective is to demonstrate one's own ability in order to appear capable. Conversely, believing that intelligence is malleable produces a learning goal, or a goal to increase one's own intelligence. These goals are important because people behave very differently depending on whether they are primarily motivated to appear smart or to

become smarter (Elliott & Dweck, 1988). People who have a performance goal are likely to respond unproductively to setbacks, which Dweck characterizes as a helpless learning style. After experiencing difficulty on a task, they typically will feel distress, decrease effort, work less effectively, and attribute poor performance to their own ability. On the other hand, people with learning goals are more likely to have a mastery-oriented learning style. They will get less upset and show less change in their effort and work quality when facing obstacles and will attribute poor performance to more controllable factors such as their effort (Diener & Dweck, 1978). These behavioral differences are consistent with their respective goals. Someone who has a performance goal will respond negatively and disengage quickly after a setback because being seen to struggle undercuts the goal to look smart but someone with a learning goal will persevere because trying different approaches to a problem provides an opportunity to learn something new. These goals influence behavior in other ways. For example, people with a performance goal view the exertion of effort negatively, often avoid challenges, and seek tasks at a level of difficulty where they are confident of success, while people with a learning goal view exertion positively and seek challenging tasks regardless of whether they expect to succeed (Elliott & Dweck, 1988).

The mastery-oriented learning style seen in people who have a growth mindset is beneficial to learning in many ways. It attracts people to challenging situations where they can develop new abilities and leads them to work with greater effort, persistence, and effectiveness. Because people with a growth mindset view effort to be positively related to success, they are also more likely to take steps to improve in areas where their own performance is currently lacking (Hong, Chiu, Dweck, Lin & Wan, 1999). There is clear evidence that viewing intelligence with a growth mindset is associated with better performance on objective measures of academic achievement. For example, Blackwell, Trzesniewski, & Dweck (2007) found that, in comparison to their peers with a fixed mindset, students who reported having a growth mindset at the start of seventh grade earned higher grades and had a stronger trajectory of improvement in math during seventh and eighth grade, and that their greater achievement was due to differences in their behavior and approach to the material. Specifically, students with a growth mindset were less likely to attribute failures to their own ability, more likely to respond to setbacks in a productively effortful manner, and more likely to view effort positively. Having a growth mindset also seems to attenuate the negative impact of factors that are typically associated with lower academic achievement, such as stereotype threat (Aronson, Fried, & Good, 2002) and poverty (Claro, Paunesku, & Dweck, 2016).

Relatively brief educational interventions that emphasize the malleability of human intelligence (e.g. Blackwell, Trzesniewski, & Dweck, 2007; Paunesku et al., 2015) can cause people to adopt a stronger growth mindset about intelligence. A recent area of emphasis has been the development and evaluation of such interventions as a way to improve educational outcomes, especially among students at risk for underachieving. Although this is a relatively new area of research, there is promising evidence supporting the idea that promoting growth mindsets can lead students to work more effectively and achieve better academic outcomes.

How Mindsets Are Formed

People begin to form beliefs about whether human characteristics are fixed or malleable in childhood. Receiving feedback about one's own performance is an important context for the development of these beliefs. Kindergarten-age children already differ in whether they view badness to be a fixed or malleable quality, and those who see it as fixed also tend to show many of the other helpless behaviors that are typically seen in people with a fixed mindset (Heyman, Dweck, & Cain, 1992). Children who were especially sensitive to criticism from an adult were more likely to view badness as fixed and also were more likely to respond negatively to setbacks, to attribute poor performance to their own abilities, and to not want to continue the task for which they were criticized. Feedback that is focused on personal qualities, such as skill or intelligence, is more likely to foster a fixed mindset and helpless behavior than feedback that is focused on the process (e.g. effort or the methods used) or outcome, and this is the case regardless of whether the feedback is positive or negative (Kamins & Dweck, 1999). Receiving person-focused feedback is detrimental because it leads people to connect their self-esteem too closely to the outcome of their latest endeavor. With this sense of contingent self-worth (see also Carl Rogers), people become overly concerned about the evaluation their own performance and the avoidance of failure and often forego potentially valuable opportunities that might not offer certain success. Despite the widely accepted belief that it is beneficial to praise people for their intelligence, doing so, in fact, has many negative consequences; it makes people adopt a fixed mindset and helpless learning style, eschew information about how to improve in favor of purely evaluative feedback, and even misrepresent their own performance in order to appear successful (Mueller & Dweck, 1998). Praising a person's effort or approach to a problem is preferable because it will foster a growth mindset and more productive mastery-oriented behaviors.

Extensions Beyond Intelligence

In addition to intelligence, people have implicit beliefs about many other human qualities that also affect their behavior and cognition in important ways. For example, people's social judgments are influenced by whether they have an entity theory of personality, believing that traits are fixed and unchanging, or an incremental theory, believing that it is possible for personality to change over time. People with an entity theory make stronger conclusions about a person's disposition from brief observations of behavior, assume that others' behavior will be more consistent over time, and have greater confidence in their own predictions about how others will behave (Chiu, Hong, & Dweck, 1997). People with an entity theory are also more likely to support extreme punishment for others who have behaved badly (Erdley & Dweck, 1993), to endorse stereotypes and use them when making social judgments, and to view outgroup members negatively (e.g. Levy, Stroessner, & Dweck, 1998).

Although much of the research in this area has focused on beliefs about whether attributes are fixed or malleable, implicit beliefs can differ on other dimensions as well. Some people believe that willpower is a limited resource that can be depleted by the exertion of

self-control (see Self-Control) and others believe that it is not limited and the strength of one's willpower does not fluctuate depending on prior effort (e.g. Job, Walton, Bernecker, & Dweck, 2015). People who view willpower to be limited are more likely to show ego-depletion, which is a decrease in the ability to exert self-control following prior effort, while people with an unlimited view did not show this kind of a decline. People with an unlimited view also seem to have better self-control in demanding situations and perform better on objective outcomes that require self-control, such as time management and grades.

Flow

Expression and Applications

Jeanne Nakamura[1] and Dwight C. K. Tse[2]

[1] *Claremont Graduate University*
[2] *The Chinese University of Hong Kong*

Csikszentmihalyi (1975, 1990) introduced the concept of flow to describe the subjective experience that is characterized by focused attention on the activity at hand, merging of awareness and action, loss of self-consciousness, distortion of time perception, increased sense of control, and autotelic experience (i.e. the experience of the activity being intrinsically rewarding; *auto* = self, *telos* = goal). He also suggested that people are more likely to experience flow if the activity provides perceived balance between challenges and skills, clear proximal goals, and immediate, unambiguous feedback.

On the one hand, research has consistently found people reporting flow across activities and contexts, suggesting that the capacity to experience flow is almost universal (Nakamura & Csikszentmihalyi, in press). On the other hand, research also illuminates individual differences in the frequency and the intensity of flow experience. For example, Fullagar and colleagues' Experience Sampling Method (ESM) studies in 2009 and 2015 revealed significant variation in flow intensity across individuals.

Conceptualization and Operationalization

Flow researchers have conceptualized individual differences in flow differently. For example, flow proneness or flow propensity refers to individual differences in the frequency of flow experience in daily life. According to Ullén and colleagues (2012), people who are high in flow proneness experience flow across work, leisure, and maintenance (i.e. household work and other routine chores) domains. People's proneness to experience flow (i.e. the frequency of flow experience) in a specific domain is sometimes referred to as dispositional flow (e.g. Jackson & Eklund, 2002). Often-studied domains include sports, music, and education.

Csikszentmihalyi (1975) first introduced the concept of an autotelic personality to describe people who enjoy what they are doing across contexts, regardless of extrinsic rewards. The posited characteristics of autotelic people include responsiveness to intrinsic

rewards, attentional control, actively pursuing flow experiences, approaching activities with a sense of discovery, and low ego involvement. Autotelic personality is associated with the possession of metaskills including curiosity and interest in life, persistence, and low self-centeredness (Nakamura & Csikszentmihalyi, in press).

Self-report questionnaires are commonly employed to measure flow proneness, dispositional flow, and autotelic personality. The Swedish Flow Proneness Questionnaire (SFPQ; Ullén et al., 2012) measures flow proneness by assessing respondents' frequencies of experiencing flow in daily work, leisure, and maintenance activities. The Dispositional Flow Scale-2 (DFS-2; Jackson & Eklund, 2002) was developed to measure dispositional flow in a domain specified by researchers. Later, the DFS-2 was modified to measure autotelic personality, indicated by a person's frequency of flow experience in "any activity in life" (Johnson, Keiser, Skarin, & Ross, 2014; Ross & Keiser, 2014).

Other self-report scales used to operationalize dispositional flow and flow proneness include the Flow Questionnaire (FQ). It differentiates individuals who report flow-like experience from those who have never experienced flow and assesses people's frequency of pursuing their preferred flow activities (Csikszentmihalyi & Csikszentmihalyi, 1975; Delle Fave, Massimini, & Bassi, 2011). Also commonly employed in flow research are the Flow Short Scale (FKS) developed by Rheinberg, Vollmeyer, and Engeser in 2003, Jackson, Martin, and Eklund's Short Flow Scale and Core Flow Scale, and Bakker's Work-related Flow Inventory, all developed in 2008. These scales are considerably shorter than the SFPQ and DFS-2.

Another conventional measure of autotelic personality or flow proneness employs the ESM. Participants in an ESM study receive signals at random times in the day and immediately complete a brief self-report form about their feelings or other momentary experiences. Autotelic personality has been measured by the proportion of a participant's responses in which they report high perceived challenge and skill levels simultaneously (i.e. flow-conducive conditions) or high intrinsic motivation under these conditions.

Psychological and Personality (Trait) Covariates

Subsequent research has shown that individual differences in flow are associated with various personality traits, although the underlying mechanisms relating flow experience to personality are still relatively unclear. A coarse classification divides the current literature on traits and flow into two sets: one set of studies has examined the relation of the Big Five personality traits to individual differences in flow; a second body of research has explored traits theoretically linked to flow, such as mindfulness and achievement motives.

Among the Big Five traits, one would predict that autotelic personality is related to conscientiousness because self-discipline, achievement-striving, and competence may foster goal-setting and effective goal pursuit. Indeed, conscientiousness has been consistently shown to be associated with flow proneness by Ullén and colleagues, Johnson and colleagues, and Ross and Keiser. Relatedly, researchers such as Teng in 2011, Cermakova and colleagues in 2011, and Kuhnle, Hofer, and Kilian in 2012 found that temperament factors of persistence, attentional control, and self-control were positively associated with flow experience. Moreover, a 2008 experiment by Keller and Bless showed that people high

(vs. low) in action-state orientation – the ability to stay focused whenever necessary to complete the activity at hand – were more sensitive to the perceived balance between challenges and skills. These results indicate that self-regulatory capacities are essential to flow proneness.

Conversely, neuroticism is expected to be inversely associated with autotelic personality because negative emotions, impulsiveness, and self-consciousness may disrupt sustained concentration. The negative relationship was consistent across studies conducted by Ullén and colleagues, Johnson and colleagues, as well as Ross and Keiser. Asakawa's 2010 study also revealed that autotelic people had lower trait anxiety. These results indicate that neuroticism is detrimental for entering and sustaining flow in daily activities.

It is less clear theoretically how autotelic personality relates to extraversion, agreeableness, and openness to experience. Empirically, there is mixed support for a positive relationship of autotelic personality to extraversion; there is also no consistent empirical evidence for a significant relationship to agreeableness or openness to experience. More research is necessary to clarify these relationships.

In addition to the relationship between flow proneness and the Big Five personality traits, individual differences in flow are shown to be associated with psychological resources such as self-efficacy, mindfulness, and internal locus of control. First, research has consistently found a positive association between flow experience and self-efficacy or self-esteem among indoor and outdoor rock climbers, college students, as well as PhD students and faculty members in studies conducted by Schüler and Nakamura in 2013, Asakawa in 2010, and Hosseini and Fattahi in 2014, respectively.

Second, (trait) mindfulness is related to flow proneness conceptually and empirically. Moore in 2013 reported a positive relationship between flow proneness and trait mindfulness. However, Sheldon, Prentice, and Halusic conducted a series of studies in 2015 and suggested that mindfulness was associated with only the sense of control dimension of flow positively while associated with the absorption dimension of flow negatively. Future researchers should be mindful that different facets of flow experience may be associated with mindfulness differently.

Third, people with strong internal locus of control (LOC) believe that their effort can influence the outcomes of their actions. In 2008, Keller and Blomann found that compared to people with low internal LOC, people with high internal LOC reported more involvement and enjoyment when playing games that had balanced levels of challenge and skill. The result supports the "person-activity fit" hypothesis that people's dispositional belief in their own control favors flow activity that provides them a strong sense of control in the moment.

Finally, research has addressed the relations of motives to flow. In 2005, Eisenberger and colleagues found that workers who were high in need for achievement reported optimal experience when challenge and skill levels were simultaneously high. Subsequent research on achievement flow motive – defined as the motivation to both seek and master difficulty – by Baumann and Scheffer in 2010 and Busch and colleagues in 2013 revealed that (implicit) achievement flow motive was positively associated with flow experience among German business students, with intrinsic motivation among US college students, and with educational attainment among German, Cameroonian, and Costa Rican adults. In addition, Schüler in 2010 found that sports players whose implicit and explicit

achievement motives were congruent were more likely to report flow than those whose motives were incongruent. Also, research conducted by Moneta (2004) on work and Abuhamdeh and Csikszentmihalyi on leisure suggested that flow is associated with trait intrinsic motivation positively; moreover, trait intrinsic motivation amplifies the positive effect of challenge on enjoyment in intrinsically motivated activities.

Demographic, Biological, and Cultural Differences

Demographically, males and females differ in the activities where they are more likely to experience flow. For instance, in ESM studies by Shernoff and colleagues in 2000 and 2007, US adolescent girls reported more flow experience than boys in the classroom and in life overall. Males, on the other hand, have consistently reported more flow experience than females when on the internet or playing video games. In addition to gender, Collins and colleagues in 2009 found that age was negatively associated with average quality of flow among older adults. However, the evidence of age differences in flow is not adequate for a definitive conclusion currently.

Biologically, flow proneness may be heritable to a certain extent. In a 2012 twin study, Mosing and colleagues concluded that flow proneness was moderately heritable, with similar genetic factors influencing flow proneness in work, leisure, and maintenance activities. In addition, the initial results of neurobiological research on flow suggest that individuals who are prone to flow may be biologically or neurologically different from those who are not. For instance, in 2013, de Manzano and colleagues reported that availability of dopamine D2-receptors in the striatum (particularly the dorsal striatum) was associated with flow proneness positively. Interestingly, consistent with the findings on flow and personality traits, striatal D2-receptor availability is associated with lower impulsivity, lower neuroticism, higher emotional stability, and higher conscientiousness.

Furthermore, Wolf and colleagues in 2015 showed that compared to amateur table tennis players, professional players had lower left-brain activity and stronger right-temporal premotor activity coherence, which was positively associated with flow experience among professional players. Verbal-analytical processes are associated with left temporal brain activity, suggesting professional athletes were able to inhibit the interference of irrelevant verbal-analytical processes and attend fully to controlling their motor actions when playing. Such ability may potentially contribute to their flow experience in sports.

Culturally, as Massimini, Delle Fave, and colleagues have theorized and extensively documented, people with different backgrounds also show differences in flow. First, culture influences parenting style, and thereby the prevalence of flow experience among children. For instance, studies in 1998 and 2001 by Asakawa and colleagues showed that Asian-American parents were more likely than Caucasian-American parents to (1) make major academic decisions for their children and (2) support their children's autonomy on what courses to take. Asian-American adolescents appeared to benefit from this parenting style: They reported more flow experience in learning activities than their Caucasian counterparts, according to Shernoff and Schmidt's 2008 research. These results suggest that culture affects students' learning experience potentially through the mediation of parenting style.

Culture also affects how people perceive and approach challenges and hence the optimal challenge-skill ratios are different across cultures. Asakawa and Moneta, respectively, showed that while autotelic Japanese college students reportedly spent more time on challenging tasks, the optimal challenge-skill ratios for US twelfth graders and Hong Kong college students were inclined toward skills. These findings cannot be explained by the East–West cultural dichotomy. Therefore, more cross-cultural research on flow is needed to understand the underlying mechanism of cultural influence on flow.

Flow and Physical and Psychological Health

Some research on individual differences in flow and physical and mental health has begun to illuminate the relationship between them. First, early qualitative investigations by Massimini suggested that people can experience flow despite physical disability. Later research by Delle Fave and colleagues has supported this claim. For example, in a 2014 ESM study conducted by Sartori and colleagues, rehabilitation activities were characterized by engagement, concentration, sense of control, and perceived balance between challenges and skills among hospitalized clients with orthopedic problems, neurological disorders, or chronic obstructive pulmonary disease. These results suggest that people's capacity for experiencing flow exists regardless of their physical conditions.

As for psychological health, in a 1992 psychiatric case study reported by Delle Fave and colleagues, identifying and encouraging participation in a flow activity contributed to successful treatment of an agoraphobic patient, suggesting the potential therapeutic contribution of flow. In addition, correlational research has associated individual differences in flow experience with positive psychological well-being dimensions such as life satisfaction, personal growth, and *jujitsu-kan* (fulfillment, in the Japanese context). These promising results call for further experimental research to disentangle the causal relationship between various psychological health conditions and flow experience.

Conclusion

Individual differences in flow constitute a fertile area for both theoretical and empirical work. Active areas of current research include the nature of autotelic personality and the mechanisms by which it relates to experiencing flow. Future areas of research might include the relation of flow to physical and psychological health conditions.

Personality in Military Settings

Dustin Wood[1], Peter D. Harms[1], and Paul B. Lester[2]

[1] *University of Alabama*
[2] *Research Facilitation Laboratory, US Army, Office of the Deputy Under Secretary of the Army (O/DUSA)*

History and Personality Predictors

The military experience can be thought of as a particularly intense context for personality-environment transactions. Involvement in combat represents one of the more extreme experiences an individual may encounter, and many books, movies, and documentaries have examined the impact of wartime experiences on the military service members, military leaders, and their families. Conversely, the characteristics of military service members and military leaders are regularly understood as playing a determining factor in success or failure on the battlefield. For instance, most historians agree that Union Army's progress against the Confederacy in the American Civil War was slowed considerably by the leadership of the narcissistic and overly cautious General George McClellan, and then accelerated by the leadership of the more dutiful, cognitively complex, and assertive General Ulysses S. Grant. More generally, Dixon (1976) argued that characteristics in military leaders such as mental rigidity and dogmatism, ego fragility, and the fear of failure played pivotal roles in some of the most epic military failures of the twentieth century.

The body of theory and research exploring linkages between psychological characteristics to military experiences and outcomes is long. Indeed, the idea that military personnel should be selected on the basis of their personality characteristics for thousands of years. Plato described effective "Guardians" as possessing attributes such as "quick senses to detect an enemy," being "fearless and indomitable in the face of any danger" while also being "gentle to their own people and dangerous only to enemies." Indeed, he proposed using tests in childhood to identify those whose character was well-suited for military service. Some of the earliest tests of individual differences in modern psychology were developed primarily to help improve selection procedures the military (e.g. Ellis & Conrad, 1948). More recent research efforts such as Project A (McHenry, Hough, Toquam, Hanson, &

Ashworth, 1990) have broadened the range of predictors and outcomes examined, and linked these more directly to frameworks found outside of the military.

Here, we will review how personality traits appear to relate to military outcomes such as performance, attrition, training success, and leader emergence, and how military experiences seem to affect personality traits over time.

Personality Predictors of Military Performance

Predictors of military performance appear to parallel predictors of performance in other contexts. For example, both mental ability and aspects of conscientiousness are strong predictors of military performance (McHenry et al., 1990). There is even evidence that personality traits may be stronger predictors of performance in military settings than nonmilitary settings. In particular, higher levels of organizational citizenship behaviors (OCBs) and lower levels of counterproductive work behaviors (CWBs) have been associated with higher levels of conscientiousness as well as cooperativeness, attention-seeking, and preference for physical activity (Drasgow et al., 2012).

Training

There are indications that certain psychological characteristics function similarly to alter the rate at which recruits learn skills in training. Traits such as ambition, achievement motivation, and engagement and enjoyment of educational and intellectual activities have been associated with more effective training outcomes (Driskell, Hogan, Salas, & Hoskin, 1994). Successful completion of the Army's rigorous Ranger training program has been linked with a range of traits related to well-being and resilience, such as optimism and adaptability, and lower tendencies toward depression and overgeneralizing negative events (Lester, Harms, Herian, & Sowden, 2015).

Attrition

The costs of military service members leaving the military before their term of service is complete (e.g. by quitting or being discharged) can be crippling given the costs associated with recruiting and training. Consequently, there has been increasing work to identify predictors of attrition. In particular, a number of studies have identified aspects of neuroticism or preexisting mental disorders as being predictive of early discharge (Fiedler, Oltmanns, & Turkheimer, 2004).

Leader Emergence and Effectiveness

Given the large role that leaders can have on subordinates and on the attainment of organizational goals, better identifying the qualities that are predictive of effective leadership could improve in a range of performance-related outcomes for the military as a whole. As with the military outcomes thus far discussed, there are indications that the relationships linking personality to leadership outcomes are similar to those found in nonmilitary

settings. For instance, studies of military cadets have frequently found positive leadership outcomes to be associated with the Big Five dimensions of extraversion and conscientiousness, and less regularly with openness, agreeableness, and emotional stability (Chan & Drasgow, 2001).

Beyond the Big Five, ratings of military leadership have been positively associated with dimensions such as ambition, egotism (e.g. a sense one is superior to others), self-esteem, prudence, and educational interest, but negatively with impression management and manipulativeness (Johnson, 1999). Early-career promotions in the US Army were associated with higher levels of psychological resources such as optimism, engagement, positive affect, and lower negative affect and loneliness (Lester, Harms, Bulling, Herian, Beal, & Spain, 2011). And longitudinal studies of cadets at military academies have shown that developing leadership skills is positively related to characteristics such as narcissism, excessive attention to detail, and stringent adherence to rules, while paranoia, unconventional thinking, and indifference negatively impact leadership development (Harms, Spain, & Hannah, 2011).

Mental Health Outcomes

Working within the military is almost uniquely associated with the experience of sanctioned killing, and of greatly increased mortality risk. Both of these can have large and enduring psychological effects that are still not fully understood. A large number of studies have found links between military experiences and mental health problems, particularly if the individual's military experience involved combat. Combat-related experiences appear to substantially increase rates of antisocial behaviors and may more than double rates of posttraumatic stress disorder (PTSD) symptomology. For example, a study of Vietnam veterans found higher levels of combat exposure to substantially increase measures of a range of negative psychological outcomes taken nearly 20 years later, such as meeting criteria for PTSD and antisocial personality disorder (Barrett et al., 1996).

Although there are clear main effects of combat experiences on the development of negative psychological and behavioral characteristics, it is also clear that some individuals are more susceptible to these effects than others. For instance, scores on several MMPI dimensions taken prior to military experience predicted greater PTSD symptoms among veterans later in life (Schnurr, Friedman, & Rosenberg, 1993). More recently, a large study of US Army soldiers found individuals scoring lower on measures of positive psychological health, such as optimism, positive affect, and adaptability tended to have increased risk of drug abuse and suicide while serving in the military (Brady, Credé, Harms, Lester, & Bachrach, 2019; Krasikova, Lester, & Harms, 2015).

Effect of Involvement in Military Settings on Personality Development

Military culture departs substantially from civilian cultures, with a particularly strong hierarchical culture valuing adherence to a chain of command. Recent studies have begun investigating how such a culture impacts personality development. For example, longitudinal research has shown that military service attenuates the normative tendency to increase in agreeableness in early adulthood (Jackson, Thoemmes, Jonkmann, Lüdtke, & Trautwein, 2012). Another

study showed that levels of neuroticism tended to decrease following basic military training while levels of conscientiousness tended to increase (Vickers, Hervig, Paxton, Kanfer, & Ackerman, 1996).

Interventions to Develop Psychological Resources/Skills

There have been increasing efforts to identify the psychological resources that can help military personnel cope with the stresses associated with military life. For example, the Comprehensive Soldier and Family Fitness (CSF2) program initiated by the US Army consisted of specialized resilience training using noncommissioned officers to train other soldiers within their unit. The program showed some effectiveness in buffering soldiers against stress-related disorders, with soldiers showing lower levels of mental health problems and substance abuse (Harms, Herian, Krasikova, Vanhove, & Lester, 2013). Similar results were found in a recent meta-analysis of resilience training programs in the military context (Vanhove, Herian, Perez, Harms, & Lester, 2015).

Current and Emerging Issues

Recent military conflicts have seen a number of new roles and challenges faced by military personnel. For example, recent military conflicts have seen a dramatic increase in the role of improvised explosive devices (IEDs) and drones in combat, and the military has been tasked to play greater roles in nation-building, which have been accompanied by changes in military tactics. There are already indications that these new military settings may shape psychological characteristics in perhaps unexpected ways. For instance, drones operators show heightened risk of PTSD symptomology, despite the fact that those operating drones are not subject to the same physical risks as military service members serving in "boots on the ground" positions within combat zones (Chappelle, Goodman, Reardon, & Thompson, 2014). As the military setting continues to evolve, it will be necessary to evaluate the extent to which our understanding of the psychological predictors and outcomes of experiences obtained from previous research will generalize to these emerging contexts.

Personality and Educational Outcomes

Amber L. Davidson[1], Eric D. Heggestad[1], and Haley M. Woznyj[2]

[1] *University of North Carolina at Charlotte*
[2] *Longwood University*

The relationships between individual differences and academic performance have long been of interest to psychologists. Early efforts focused largely on the role of cognitive ability factors in academic performance, with a now long line of research suggesting that intellectual ability is a strong predictor of academic achievement and performance. However, scholars have also long recognized that non-ability factors, such as personality characteristics, are also related to academic achievement and performance. For example, 75 years ago, Daniel Harris (1940) argued that personality traits could be used to predict academic performance, though the research base at the time was inconsistent and plagued by methodological flaws and variability in how personality was conceptualized. As broad categorizations of the personality trait domain have come into focus (i.e. the Five Factor Model) and meta-analytic techniques have become more accessible and refined, there is an increasing base of evidence that student personality traits are associated with levels of academic performance.

Academic Performance Outcomes

Academic success has been defined in a number of ways, though the three most common metrics are grade point average (GPA), performance on an exam, or reputational evaluations such as teacher, peer, or self-report ratings of grades. The most commonly used of these has been GPA, as it has important implications outside of research (e.g. a selection tool for higher education or post-graduation employment). The metric, however, has limitations; it is often susceptible to inflation and can be calculated differently across educational institutions. Exam performance, which can include standardized tests or tests given as a course requirement, is most often used as an indicator of academic success when the research takes a shorter-term perspective on success. Finally, academic success measures can also include reputational metrics that assess perceptions of the academic success of the

student as judged, or rated by teachers, peers within the learning environment, or the student him or herself. A meta-analysis by Nathan Kuncel (2005) and his colleagues showed that student self-reports of GPA are highly correlated with GPAs of those students obtained from institutional records.

Student Populations in the Research Base

Much of the research on personality and academic performance has been conducted on students in post-secondary educational contexts, most likely due to the relatively easy access to this population. A reliance on post-secondary samples is a limitation in that the results are not likely to generalize to other educational levels. As social and learning contexts change across educational levels (e.g. from primary to secondary educational contexts), the role of personality in academic performance is also likely to change. For instance, there is likely to be less variation in intelligence scores among college students than there is among students in lower educational contexts, suggesting that non-ability factors may be more important in predicting academic performance within post secondary education contexts.

Additionally, research in applied psychology has shown that relationships between personality characteristics and workplace performance are higher in jobs where the workers have greater levels of autonomy. Applying these findings to educational contexts suggest that as students progress to secondary and post secondary educational contexts, where there are increasingly higher levels of student autonomy, the relationships between personality characteristics and performance may grow stronger. Most of the relationships we discuss in the rest of this entry are based on undergraduate students. We will draw attention to those occasions where findings are based on samples from other educational levels.

Broad Traits and Educational Outcomes

Although other perspectives exist, the Big Five taxonomy is currently the dominant perspective on the organization of personality traits (see entry on the Big Five). Of the Big Five traits, the strongest relationships with academic performance have been observed for the trait of conscientiousness. At the post secondary level, a meta-analysis by Michelle Richardson (2012) and her colleagues found that the corrected correlation between conscientiousness and GPA was .23 across 69 studies. Similar findings were reported by Arthur Poropat (2009) in a meta-analysis of 35 samples of secondary students. Specifically, he reported a (corrected) correlation of .21 between conscientiousness and academic performance. Both of these meta-analyses also looked at the relationship between intelligence and academic performance. Interestingly, the corrected values for the intelligence-academic performance relationship (.21 in the analysis by Richardson and colleagues and .24 in the analysis by Poropat) are very similar to the relationships between conscientiousness and academic performance, indicating that conscientiousness is as predictive of academic performance as intelligence at the secondary and post secondary levels.

The broad trait of openness has also been shown to be related to academic performance, though the magnitude of the relationships for this trait are notably lower than those for conscientiousness. For example, the corrected correlation between openness and GPA was .09 in the Richardson meta-analysis and .12 in the Poropat (2009) meta-analysis. Relationships nearer to zero have been found for the remaining Big Five traits of agreeableness, extraversion, and neuroticism.

Narrow Traits

According to Lewis R. Goldberg (1981), who first referred to the five broad trait dimensions as the "Big Five," the use of the term "Big" was meant to communicate the idea that these five trait domains are broad in their nature. As such, narrowly defined traits can be identified within each of the broad trait dimensions. The breadth of the Big Five traits can hamper their predictive capabilities, particularly when some aspects of the broad trait domain are less tightly linked to the criterion of interest than are other aspects. Thus, it is common for the more narrowly defined traits to have as strong or stronger predictive relationships with criteria than the broader trait domains.

Achievement Motivation

The broad trait of conscientiousness is often thought to consist of two more narrowly defined traits, achievement and dependability. The achievement aspect of conscientiousness captures a person's tendency to set and strive for goals, a desire to accomplish difficult things, and a focus on task mastery. Numerous studies and a meta-analysis by Spangler (1992) provide evidence that students with higher levels of achievement motivation tend to have higher levels of academic performance. The observed relationships have tended to be rather modest, however, with values often falling between .13 and .18.

Goal Orientation

In their work with primary school children, Carol Dweck and her colleagues (1988) observed that children tended to react to failure differently. Some children tended to experience negative affect, a subsequent aversion to the task, and decreased levels of performance when continuing to work on the task. Dweck and her colleagues suggested that these children adopted a "performance goal," such that performance on the task was a demonstration, to themselves and others, of their competence. Children with a performance goal determined success by comparing their performance to that of others; they perceived themselves as successful when they did better than others. In contrast, other children reacted to failure by increasing their effort, seeing failure as an obstacle to be overcome. These children tended to show increased levels of performance over time. Dweck and her colleagues suggested that these children had adopted a "learning goal," such that performance on the task was an indication of how well they had mastered the task to this point in time. Children with a learning goals determined success by comparing their performance with how they had done in the past and assessing the extent of improvement.

Early on in this line of research, the learning and performance goals were conceptualized as goals that the students would adopt at a particular point in time when working on a particular task. As the research progressed, however, scholars began to conceptualize these state goals as stable traits, referring to them as learning goal orientation and performance goal orientation. Learning goal orientation (sometimes referred to as mastery goal orientation) is the tendency to approach achievement situations with a focus on improvement and learning, and, as such, is similar in nature to achievement motivation. Performance goal orientation is the tendency to set goals about doing better than others. Subsequent research suggested that performance goal orientation could be better conceptualized as two distinct traits. Performance-prove orientation is the tendency to focus on being better than others while performance-avoid orientation is a tendency to exert effort directed toward avoiding failure or being perceived as incompetent.

Like achievement motivation, the relationships between the three goal orientation traits and academic performance are not very strong. In a meta-analysis, Chiungjung Huang (2012) found relationships between the goal orientations and academic achievement of .13, .07 and –.12 for the learning, performance-prove and performance-avoid goal orientation traits, respectively. Note that the correlation for learning goal orientation is very much in line with what has been reported for achievement motivation.

Test Anxiety

Coming out of a tradition of David C. McClelland's notion of the fear of failure, test anxiety represents a tendency to experience worry, anxiety, and physiological reactions to testing or other evaluative situations. Test anxiety is related to the Big Five trait of neuroticism. While neuroticism has not shown relationships with academic performance, test anxiety has. In the meta-analysis by Richardson and colleagues, test anxiety was found to correlate –.21 with GPA across 29 studies.

Personality as a Distal Predictor

The accumulated evidence generally suggests that the relationships between personality characteristics and academic performance outcomes tend to be rather modest in magnitude. Such findings should not be surprising and should not be considered disappointing. First, academic performance outcomes, such as GPA, are clearly complex indices of success that are influenced by a large number of factors, including intelligence, personality, personal values, socio economic factors, and family situations, among many others. Second, much of the research has taken a piece meal approach, whereby bivariate relationships between a single trait and a single outcome are the norm. However, individual traits may each predict unique variation in the outcomes such that considering multiple traits at the same time may result in higher levels of explained variance. Going a step further, some of the traits may interact with one another as well, explaining even more variance. Third, personality traits are likely best conceptualized as distal determinants of academic performance. As such, the influence of these traits is most likely to be indirect through more proximal processes. Considerable research indicates that the influence of personality is most likely to occur through motivational processes, such as self-efficacy, goal setting, state goal orientation, and the like.

Personality and Law Enforcement

Majeed Khader and Cherie S. Y. Goh

Ministry of Home Affairs, Singapore

The First Wave of Personality in Law Enforcement: Looking for a Police Personality

The first wave of research on personality in law enforcement compared police and "general population" personality norms and examined if there was a personality "type" that was attracted to policing as a career vocation. This was the "predisposition hypothesis." Studies typically compared police officers or applicants with general others or norms in terms of psychological or personality characteristics. Comparisons were also made with other criminal justice personnel, nuclear submariners, air force pilots and even with habitual criminals. Themes explored focused on clinical and pathological issues such as conservatism and authoritarianism, racial prejudices, mental unfitness, cynicism, corrupt attitudes, lowered intelligence levels as well as masculinity. There were limitations to these studies, and they were mainly the lack of matched controls and that the studies based their conclusions on the results of instruments designed for clinical use rather than for normal populations.

The more commonly employed instruments during this wave were the Minnesota Multiphasic Personality Inventory (MMPI), the Eysenck Personality Questionnaire, 16 Personality Factors (16PF), Myers-Briggs Type Indicator (MBTI), and California Psychological Inventory (CPI). One study found that police applicants applying to the London Metropolitan Police were higher on extraversion when compared to general norms while the average police candidate was high in control, toughmindedness, and independence and low on anxiety, based on a large aggregated sample of 15,000 candidates for positions in various law enforcement agencies in the United States. Using the MBTI with a US police organization, a study found that police applicants were extraverted, rational, nonintuitive, decisive, rigid, personal, and organized. The same profile was seen for Australian police recruits. Significantly, ISTJ (introversion, sensing, thinking, and judging) was noted to be common among senior police officers, implying that senior officers compared to junior officers may be more introverted, introspective, thorough, decisive, logical, attentive to detail, and well adapted to routine. Other studies found that the CPI scales of

responsibility and self-control were substantially higher for the law enforcement samples than the normative sample, while scales of flexibility, sensitivity, and creative temperament are substantially lower for the law enforcement sample.

The Second Wave: Looking for Successful Police Personalities

The second wave of research looked at "successful" and "unsuccessful" police officers, asking if they had different personalities. Studies have found a significant correlation between MMPI scales and outcomes such as serious misconduct, frequency of car accidents, aggressiveness, and performance. MMPI-2-RF scores were also correlated with stress problems, performance problems, discipline issues, and communication skills. On the other hand, some studies reported that those who graduated from police academy training were more outgoing, stable, venturesome, confident, controlled, and relaxed.

Significant correlations have been found between several CPI scales, supervisory ratings, during training and on-the-job, supervisory ratings of leadership and overall suitability for police work (i.e. socialization, communality, and flexibility). Interestingly, Sarchione, Cutler, and Nelson-Gray (1995) attempted to use the CPI to predict groups of officers who received disciplinary action in the course of their work. These officers scored significantly lower than other groups on scales measuring responsibility, self-control, socialization, tolerance, sense of well-being, and flexibility. Using the personality assessment inventory (PAI), Weiss and colleagues (2005) reported that the Antisocial (Egocentricity) scale predicted insubordination and citizens' complaints while the Antisocial (Stimulus Seeking) scale and Negative impression scale predicted neglect of duty.

The Inwald Personality Inventory (IPI) has been another popular instrument developed specifically to assist public safety and law enforcement agencies in selecting new officers. By itself, the predictive validity of the IPI does not appear to be strong, but coupled with the MMPI, it has been shown to predict performance well. For example, the IPI when used with the MMPI effectively classified officers who were accused of absences, lateness, and disciplinary interviews. In another study, researchers used the IPI and MMPI to predict global job performance of government security employees after nine months with a true classification rate of 77.2%.

It should be noted that many of these studies have adopted a "select-out" rather than a "select-in" approach. This may be due to the absence of strong predictors of success in police work: that is, it was easier to say which are the qualities a police officer should not have than to say which factors he or she must have. At best, the results of these studies are mixed and at worst, several contradicted each other. Despite differing results, there might be some indication that police officers who are higher on neuroticism as a personality trait (for example, hypomania, hysteria, paranoia) appear to be poor performers. Another positive improvement in the selection research is the move to select police officers using a combination of measures that are both clinically relevant and measures of normal personality. Arrigo and Claussen (2003), for example, argued that administrators could use the IPI with the NEO-Personality Inventory–Revised screen for both antisocial personality disorder and conscientiousness in police selection contexts.

The Third Wave: "Predisposition" Versus "Socialization" Studies

The third wave of research has looked at police personality asking whether it is a "predisposition" ("born") or "socialization" (canteen culture / cop culture) issue. Studies conducted have attempted to answer the question, "Which was more potent – the predisposition or the socialization factor, and how do they interact with each other?" This question is probably best studied with a longitudinal design that allows for the systematic investigation of both personality and socialization factors as they interact. Roberts, Caspi, and Moffitt (2003), for example, wrote a paper on how personality affects work and how work, in turn, affects personality for young adults aged 18 to 26. Using a sample of 1,037, they noted that adolescent personality traits, assessed at age 18, predicted the nature of young adults' work experiences over the next eight years. In turn, these same work experiences predicted corresponding changes in personality traits over the same developmental period. If the police department recruits personnel at the age of 18 or more, then it suggests that the same nature of influence between personality and work experiences is also possible for police samples. Only a handful of published longitudinal studies that investigate police officers exist, as most have been cross-sectional studies. Unfortunately, those studies did not focus on personality.

The Fourth Wave: The Big Five Framework

Personality psychology has made a remarkable comeback with the advent of the Big Five Framework. Hogan, Johnson and Briggs (1997) argued that there might be several important changes in the research that may have resulted in this. First, the traditional method of choice in selection work for industrial-organizational psychologists has always been cognitive tests, which may result in adverse impact for protected classes of employees. Well-constructed personality tests, on the other hand, are gender and race blind. The second reason for this resurgence was the appearance of the Five Factor Model (FFM) or the Big Five framework, which provided a way to organize personality measurement.

Some studies have attempted to directly measure the Big Five factors. For example, some research studies measured the Big Five using the IPI and MMPI and showed that conscientiousness was correlated with six performance criteria (probation ratings, peer evaluation, counseling cards, training ratings, and grade point average for training, and turnover). In another study looking at police applicants, 10 police experts using the NEO-Job Profiler to describe characteristics of entry-level police showed that the ideal police officer was thought to be characterized by low scores on angry hostility, impulsiveness, vulnerability, and tender-mindedness and high scores on assertiveness, competence, and self-discipline. Interestingly, while expert judges believed that high Agreeableness was not desirable, it was discovered that those who received high recommendation ratings at the interviews in fact have high agreeableness scores.

Khader (1999) used the NEO-FFI on a Singaporean sample of police officer applicants and found that when compared to a demographically similar group such as narcotics officers, police applicants were higher on neuroticism, more conscientious, and used a combination of social support and emotion-focused coping techniques. In a related study, the profiles of applicants who were accepted and rejected by police interview boards were

examined for differences in personality scores. Results showed that "accepted" applicants had lower neuroticism, higher openness, and used less emotion-focused coping. It was also found that trainees who were rated as less successful by their peers and supervisors tended to have high neuroticism and used more emotion-focused coping scales. At the same time, trainees who had higher training scores in the academy had moderate levels of neuroticism, higher extraversion and conscientiousness (N-E-C combination), used problem-focused coping styles, and had higher cognitive ability scores.

New Zealand police psychologists found promising results using the NEO-PIR and argued that the NEO offers promise "because the higher and middle order traits added incremental validity to cognitive testing" as a predictor of performance. Positive correlation coefficients between personality and performance were reported for the various personality domains and overall recruit performance after training. The NEO-PI-R facet scales also correlated with performance. Police recruits who were better performers were reliable, dependable, determined, self-confident, goal-oriented, preferred to be busy, were willing to consider new ideas, were forceful and assertive, possessed a belief that society is generally honest, possessed a tolerance for personal frustration, and were resistant to stress.

Using a large Singaporean sample of serving police officers and the NEO-FFI, Chan (2002) found that neuroticism was correlated with supervisory ratings of officers' annual performance ratings and potential for future success. He noted that conscientiousness was correlated positively with supervisory performance ratings and potential for success ratings. Several personality traits were also correlated with subjective well-being outcomes. Specifically, neuroticism, extraversion, agreeableness, and conscientiousness had significantly correlated with self-reported job satisfaction. Neuroticism was significantly correlated with organizational records of discipline cases. Neuroticism, extraversion, agreeableness, and conscientiousness were reported to correlate significantly with self-reported intention to quit.

More recently, Detrick and Chibnall (2013) found that the NEO-PI-R profile of the successful police officer applicant is characterized by very low levels of neuroticism and high levels of extraversion and conscientiousness (with average levels of openness and agreeableness).

The Big Five model is not without critics. Researchers had argued that the term *model* should not be used at all and preferred the term *approach*, and that there is a lack of theoretical explanation with respect to the five dimensions. For instance, Briggs (1989) noted that no one has a priori theoretical reason why it was these particular five dimensions rather than some other five dimensions. Despite its critics, there has been a great amount of research that has attempted to develop theoretical accounts of the Big Five.

While prior critiques of law enforcement personality research had pointed out that the psychometric instruments used were intended for clinical purposes, a myriad of research has provided evidence for the predictive validity of those tools in investigating the police personality as well as the "successful" profile. The latest introduction of the Big Five concept provides a different approach to exploring the earlier waves of research in literature. Nevertheless, research in the four waves of personality in law enforcement personnel is still ongoing.

Personality and Forensic Psychology

Mark A. Costanzo[1] and Marina L. Costanzo[2]

[2]*University of Montana*

Personality comes into play wherever people interact or make decisions. So, the law – that highly structured system where police, defendants, lawyers, jurors, and judges interact to reach decisions about guilt and liability and punishment – should be a fertile place to study personality. However, with a few notable exceptions that we describe below, psychologists who study the legal system have largely neglected the study of personality.

One key reason for this neglect of personality is that the field of legal psychology is explicitly applied. Researchers tend to be focused on assessing the effectiveness of legal procedures and on finding ways to improve the accuracy of legal judgments. For example, one of the most heavily researched areas in legal psychology is eyewitness identification. Researchers have examined the factors that influence eyewitnesses' memory of a criminal event, the type of questioning procedures that elicit accurate memories, how a suspect lineup should be constructed, and the persuasiveness of eyewitnesses when testifying in court (Costanzo & Krauss, 2018). While it might be interesting to know how the personality traits of the eyewitness shape the accuracy of eyewitness identification, the impact of personality on accuracy is likely to be negligible. More important, unlike questioning procedures or lineups, the personality of the eyewitness is not under the control of the legal system. The legal system cannot arrange for only introverts or people high on conscientiousness to be around to observe a crime. Because the legal system has little control over the personality characteristics of victims, witnesses, defendants, lawyers, judges, and jurors, research on personality characteristics holds limited potential for improving legal procedures.

There are, however, a few areas where legal / forensic psychologists have found it useful to explore the impact of personality and individual differences. One of these areas is police interrogations and false confessions. Along with mistaken eyewitness identification and faulty forensic testing, false confessions are a major source of wrongful convictions (www. innocenceproject.org). Confessions researchers have sought to identify the characteristics of suspects that raise the risk of false admissions. Although the main suspect characteristics

that increase the vulnerability of a suspect – youth, cognitive impairment, and mental illness – are not personality traits, some traits have been shown to be associated with the tendency to offer false admissions. Specifically, Gisili Gudjonsson and his colleagues (Gudjonsson, Sigurdsson, & Einarsson, 2004; Gudjonsson & Pearce, 2011) have identified two personality traits – suggestibility and compliance – that increase the probability of a false confession. Suggestibility refers to a tendency for a suspect to accept information communicated during interrogation as true, and to incorporate misleading information from external sources (principally police interrogators) into personal memories of a crime. This trait puts suspects at risk because, during interrogation, police detectives often lie to suspects about the existence of incriminating evidence. This false evidence may be accepted by highly suggestible suspects and may even distort their memories of events.

The second trait identified by Gudjonsson is compliance, which refers to the tendency to acquiesce to interrogators' requests to confess to committing a crime. Highly compliant suspects may change their account of what happened in exchange for the immediate gain of being released from the intense stress of the interrogation room. The two factors underlying compliance are an eagerness to please others and a strong desire to avoid conflict and confrontation (Gudjonsson, Sigurdsson, & Einarsson, 2008). Research has demonstrated that false confessors score higher on interrogative compliance and suggestibility than non-false confessors (Gudjonsson, 2010). Although knowing a suspect's suggestibility and compliance scores cannot reveal whether his or her confession is true or false, information about such scores is sometimes provided by experts at trial to assist the trier of fact (a judge or jury) in assessing the validity of a confession.

Juries are another area of legal psychology where understanding of personality variables might be helpful. The personalities of individual jurors might be expected to influence how evidence is evaluated and how verdicts are decided. However, large-scale studies of the relationships between personality traits and verdicts have generally found only weak associations (Penrod, 1990). A few significant associations have been identified. The construct of "locus of control" has been mildly predictive of verdict in some types of cases. Jurors with a more internal locus of control (i.e. a belief that outcomes in life are largely due their own ability and effort) are somewhat more likely than jurors with an external locus of control (a belief that their outcomes in life are likely due to factors such as luck or powerful others) to acquit a corporation that has been sued by a former employee for wrongful termination or sexual harassment or discrimination. In addition, the personality trait of authoritarianism appears to have some impact on verdict decisions (Shaffer & Wheatman, 2000). Jurors who score high on measures of authoritarianism tend to be more conviction prone in criminal trials and tend to endorse longer prison sentences for crimes such as murder, rape, and child molestation. However, in cases where authority figures like police officers and corporations are being tried, jurors high on authoritarianism are somewhat less likely to convict. Finally, only one of the "Big Five" personality factors has been shown to a role in the jury room: Jurors who score high on extraversion are more likely to be elected foreperson (Clark, Boccaccini, Caillouet, & Chaplin, 2015).

Within the domain of workplace law, sexual harassment is an important area of study for legal psychologists. Much of the research in this area has focused on ways of reducing sexual harassment through employee training and modifications of the workplace

(e.g. removing sexually explicit materials, increasing the percentage of underrepresented groups, and modifying recruitment and promotion procedures) (Glick & Fiske, 2007). However, a few researchers have explored how personality encourages sexually harassing behavior. John Pryor and his colleagues have developed the Likelihood to Sexually Harass (LSH) scale as a means of assessing individual differences in the tendency to engage in illegal harassment (Pryor, 2009). Studies using the scale have found that men with high LSH scores see themselves as stereotypically masculine, support traditional female gender roles, and endorse "rape myths" (e.g. the belief that women want to be sexually overpowered). Fortunately, the tendency to sexually harass is strongly influenced by situational variables. Clear anti-harassment workplace policies can significantly reduce harassing behaviors even for employees with high LSH scores (Willness, Steel, & Lee, 2007).

Clinical-forensic psychologists interested in personality and individual differences have focused primarily on criminality, searching for correlates, and predictors of criminal behavior. Although most research has found that environmental factors (e.g. poverty, childhood abuse, unstable home life) are the main catalysts for criminal behavior, there is a long tradition of research on the criminal personality. Perhaps the most heavily researched constellation of traits in forensic psychology is labeled psychopathy. The defining feature of psychopathy is a lack of empathy and moral conscience. Psychopathy is typically diagnosed using the Hare Psychopathy Checklist Revised (PCL-R). The PCL-R measures a variety of traits common to psychopaths. These traits include the following: glibness and superficial charm, grandiosity, high need for stimulation, manipulation of others, lack of remorse, shallow emotions, callousness, lack of realistic long-term goals, failure to accept responsibility for own actions, pathological lying, parasitic lifestyle, and impulsivity (Hare, 2016). High scores on the PCL are significantly predictive of violence, and people with psychopathic traits are responsible for a disproportionate number of crimes involving deception, social harm, and violence (Skeem, Polaschek, Patrick, & Lilienfeld, 2011).

An even broader set of traits associated with criminality has been termed the *dark tetrad* (Paulhus, 2014). The four overlapping clusters of traits that constitute the dark tetrad are psychopathy, Machiavellianism (calculating manipulation of others), narcissism (grandiosity, self-promotion, and attention-craving), and sadism (enjoyment of cruelty toward others). In studies exploring the relationships between the Five Factor Model and the dark tetrad, the traits of agreeableness and conscientiousness are negatively correlated with dark tetrad traits (Furnham, Richards, & Paulhus, 2013). People possessing a dark tetrad personality usually exhibit such traits in the subclinical range – i.e. they are able to function effectively in most settings and they often escape the attention of mental health professionals. However, the callousness and empathy deficits of people possessing the dark tetrad can lead to highly destructive behavior in the workplace and a proclivity for criminal behavior (Harms, Spain, & Hana, 2014).

The study of personality and individual differences has generally been regarded as useful but not central to the field of legal and forensic psychology. In large part, this is due to legal psychology's focus on variables that can be modified to improve the accuracy of legal decision-making. However, even though personality is not under the control of the legal system, research on the role of personality in legal settings is essential for a full understanding of how psychological science interacts with the law.

Personality and Consumer Behavior/Lifestyle Analysis

Bernardo J. Carducci

Indiana University, Southeast

Classic Contributions of Personality Psychology to Consumer Behavior

One of the earliest and most influential applications of personality psychology to consumer behavior was an approach based on Freud's psychodynamic principles referred to as "motivation research." As a major force in marketing and consumer behavior from the late 1940s to the early 1960s, the field of motivational research was based on the pioneering work of Ernest Dichter, a Viennese psychologist who just happened to live across the street from Freud's famous office and settle in the United States in 1937 (Schumann, Haughtvedt, & Davidson, 2008). At its peak of popularity, motivation research attempted to uncover the deep-seated reasons for purchasing particular products and unconscious influences on decision-making. To overcome the ego's defenses, motivation researchers used many projective techniques (e.g. word association and picture-completion tests) and in-depth, psychoanalytically based interviews to get at these unconscious determinants of buying behavior (Dichter, 1949, 1964; Schumann, Haughtvedt, & Davidson, 2008).

 Motivation researchers also relied heavily on psychodynamic concepts and processes in explaining and interpreting their findings. Some of the early conclusion based on this research included these ideas: wearing suspenders reflects unresolved castration complexes, making cakes symbolizes giving birth, and people do not like to buy prunes because their wrinkled shape brings back memories of parental authority figures (Dichter, 1960). The use of motivation research principles became so popular that in 1957, Vance Packard, a major proponent of subliminal advertising, published *The Hidden Persuaders* as a means of trying to cast "a penetrating light into the murky world of the motivational researchers. It tells how these shock troops of the advertising world are subtly charting your inner thoughts, fears, and dreams so that they can influence your daily living" (p. i). However, there is now considered evidence to discredit the value and effectiveness of the use of the principles of subliminal stimulation as practiced through subliminal advertising – "public

concern over the power of subliminal advertising is quite likely unfounded. Subliminal advertising is, at best, a very weak force" (Vargas, 2008, p. 478).

Contemporary Contributions of Personality Psychology to Consumer Behavior

Although its influence as the driving force in marketing has long since waned, motivation research remains significant in its focus on the underlying reasons that people buy. It has also demonstrated the usefulness of psychological theories (Kotler & Keller, 2016) and assessment techniques (Haugtvedt, Liu, & Min, 2008) in identifying and interpreting consumer behavior patterns (Arnould, Price, & Zinkhan, 2002; Hawkins, Best, & Coney, 2001). For example, the lingering impact of motivation research is the influence of classic Freudian dream analysis on contemporary marketing research through the use of manifest and latent motives to understand the decisions of consumers (cf. Hawkins, Best, & Coney, 2001). Manifest motives are the reasons known to the consumer and admitted to the consumer researcher (e.g. "A luxury car is more comfortable and safe."). Latent motives are reasons and beliefs affecting purchasing decisions that the consumer is unaware of or very reluctant to admit to others (e.g. "This is a powerful and sexy car, which will make me look powerful and sexy, as well show off how successful I am, to others."). As in dream analysis, manifest motives are easily assessed with direct questions (e.g. "Why did you by this car?") while an assortment of projective techniques (e.g. sentence completion, word association, picture response construction techniques) are used to reveal the latent content of the unconscious mind of consumers in an effort by motivational marketing researchers to better understand consumer decisions and develop marketing campaigns (cf. Hawkins, Best, & Coney, 2001; Peter & Olson, 2002). As an indication of the value of such projective techniques, investigators have noted that "these techniques are gaining use again as a way to enhance and enrich the insights that can be gained from more empirical sources" (Hawkins, Best, & Coney, 2001, p. 369).

Needs and Desires Guiding Consumer Behavior

Beyond motivational factors, the emphasis on personality dynamics (e.g. needs and desires) continues to be a major force in contemporary marketing research (Arnould, Price, & Zinkhan, 2002; Berkowitz, Kerin, Hartley, & Rudelius, 2000; Kotler & Keller, 2016). Because both of these forces are represented in Maslow's hierarchy of needs (Maslow, 1954), his viewpoint is be used by marketing managers as "a macro theory designed to account for most human behavior in general terms" (Hawkins, Mothersbaugh, & Best, 2007, p. 364). Marketers and others interested in trying to understand what drives consumers to make purchasing decisions have developed advertising campaigns for products based on their association with meeting certain need categories. When applying Maslow's hierarchy of needs to marketing campaigns, advertisers attempt to convince consumers that purchasing their products will help certain needs. Some illustrative examples of marketing campaigns, paired with each of Maslow's need categories is a series of products, along with specific marketing examples, designed to meet those specific needs.

Physiological Needs

Products designed to meet basic living requirements involving nutrition, rest, and health include food items, sleep products (e.g. mattresses, sleeping pills), exercise equipment, and medical-related supplies and insurance plans, to name just a few.

Safety Needs

Products designed to meet the needs of physical safety and security, stability, and familiarity include smoke detectors, insurance, retirement investments, seat belts, and burglar alarms, to name just a few.

Belonging and Love Needs

Products designed to meet the needs of love, friendship, affiliation, and group acceptance include personal grooming products, group-identity clothing (e.g. social causes or college sweatshirt), and restaurants, to name just a few.

Self-esteem Needs

Products designed to meet the needs for status, self-respect, superiority, a sense of accomplishment, and feelings of usefulness to others include fancy cars, designer clothing, jewelry, expensive liquor, and stylish furniture, to name just a few.

Need for Self-actualization

Products designed to meet the need for self-fulfillment and promoting one's full potential include educational programs, hobbies, vacations, sports, and museums, to name just a few.

In addition, because more than one need category can be met by a specific product, effective advertisements often operate at many different need categories. For example, advertisements marketing camping equipment and supplies could appeal simultaneously to meeting the categories of physiological needs (e.g. food), safety needs (e.g. warmth and comfort), and belonging needs (e.g. camping with others). Such examples, as well as additional research (cf. Yalch & Brunel, 1996), provide support for the validity of Maslow's viewpoint as an important tool in marketing and other business-related applications (Conley, 2007).

Attitudes and Values as the Basis of Consumer Behavior

Psychographic segmentation is a technique in which people's attitudes, interests, values, behaviors, and lifestyle patterns are used to help marketing and advertise products in a manner that fits with the social (e.g. leisure activities) and psychological (e.g. status seeking) profile of a particular segment of the buying public (e.g. young adults) for which the products are being targeted (Kotler & Keller, 2016; Peter & Olson, 2002). One of the most widely used measures of psychographics is the Strategic Business Insights' Values and Lifestyle (VALS2) Program^{TM} (http://www.strategicbusinessinsights.com/vals/). This VALS Programs survey (http://www.strategicbusinessinsights.com/vals/surveynew.shtml) seeks to explain

how and why consumers make decisions by asking individuals to indicate their degree of agreement with a series of 35 attitudinal questions such as "I am often interested in theories," "I often crave excitement," and "I like being in charge of a group." Based on their responses to these items, individuals are grouped into eight VALS types (i.e. innovators, thinkers, believers, achievers, strivers, experiencers, makers, and survivors) and three primary motivational categories upon which they based their consumer decisions: ideals, achievement, and self-expression (www.strategicbusinessinsights.com/vals/ustypes.shtml). Individuals motivated by ideals tend to use beliefs based on their knowledge and personal principles to make consumer decisions rather than on feelings, events, and the desire to seek approval from others. Individuals motivated by achievement tend to base their purchasing decisions for products and services that are likely to demonstrate a sense of success to their peers. Those motivated by self-expression tend to make purchasing decisions in the pursuit of products and social or physical activities that provide opportunities for a variety of experiences, impulsiveness, risking-taking, and the excitement.

Individual Differences as Predictors of Consumer Behavior

The tradition of individual differences utilizes the scores on specific personality measures to predict consumer behavior (Haugtvedt, Liu, & Min, 2008). The Need for Cognition (NFC) scale reflects the extent the amount of time and effort an individual will employ to thinking about a particular course of action, such as making a purchasing decision. Individuals with a high NFC tend to spend more time critically evaluating product information than those with a low NFC. The Need for Uniqueness scale (NFU) reflects the extent to which individuals desire to be independent and different from others. Individuals with a high NFU tend to view scare items as more attractive and valuable than those with a low NFU as a means of maintaining a sense of uniqueness by processing such products. The Need for Closure scale (NFC) assesses the degree to which individuals desire definite and unequivocal knowledge and information. Individuals with a high NFC are more likely to make decisions regarding certain product attributes (e.g. cost) and belief of (e.g. "price equals quality") in an attempt to achieve a sense of closure in product selection than those with a low NFC.

The Propensity for Self-reference scale (PSR) examines the extent to which individuals tend to think about their own experiences when examining product information and making purchasing decisions. While individuals with a low PSR tend to ignore the quality of the information presented to them, individuals with a high PSR may be too focused on their own beliefs and experiences to evaluate thoroughly the quality of information designed to influence their purchasing decisions. The Regulatory Focus Questionnaire (RFQ) measures the extent to which individuals are motivated to make decisions and take action based on an "orientation" (i.e. expectations of goal attainment based on past success) characterized by promotion pride or promotion prevention. Individuals scoring high on promotional pride are more likely to regulate their actions in an effort to achieve the presence or absence of a positive outcome while those scoring high on promotion prevention demonstrate a propensity to regulate their actions in an attempt to prevent or avoidance a negative consequence.

Evolutionary Psychology and Consumer Behavior

A recent development in the study of evolutionary psychology is the application of its principles to consumer behavior (cf. Saad, 2007). A framework for applying evolutionary psychology to consumer behavior is the consideration of gender differences in the underlying principles of sexual selection (see Evolutionary Theory and Personality Correlates of Mate Selection). With sexual selection, males tend to seek females for mates based on youth and beauty as an index of their perceived health and reproductive ability while females tend to seek males for mates based on their social status and ability to provide and share material resources. Consistent with those principles of sexual selection that emphasize the physical appearance of women as a means of increasing their mate potential, women tend to devote more consumer time, money, and energy than men on appearance-enhancing products and services designed to create a more youthful and healthy appearance, such as fashion and clothing concerns, body-consciousness and exercise activities, dieting programs, cosmetic surgery procedures, and tanning salon usage. Consistent with principles based on sexual selection, males tend to spend more time and money than females engaging in a variety of high-risk consumption behaviors designed to demonstrate the accumulation of resources (e.g. wealth), social status, and strength and bravery, such as engaging in more risky financial decision in an attempt to secure greater financial resources and participating in extreme thrill-seeking leisure activities (e.g. skydiving, extreme snowboarding) in an attempt exhibit strength and competitiveness.

Summary and Conclusion

In many ways, the utility of the historical developments in the study of personality psychology is reflected by the application of these improvements to corresponding advances made in the examination of consumer behavior. The earliest applications of personality psychology to consumer behavior were based, as were some of the earliest conceptualizations of personality, on the Freud's theory of the unconscious mind. As subsequent motivational viewpoints based on the expression of personal needs and values emerged in the development of personality psychology, so did their application to the study of consumer behavior. The major progress made by the contemporary tradition of individual differences and the assessment of personality traits and the more recent emergence of evolutionary psychology as a major viewpoint of personality have also had corresponding chronological applications to the study of consumer behavior. And if such a pattern continues, it is likely that the emerging focus emphasizing the neurological perspective on personality will also find an application in the burgeoning study of neuroeconomics and consumer behavior (cf. Egidi, Nusbaum, & Cacioppo, 2008).

Marketing and Personality

Sandra Matz[1] and Jacob B. Hirsh[2]

[1]*Columbia University*
[2]*University of Toronto*

The use of individual differences has a long-standing tradition in marketing theory and practice. Ever since Wendell Smith (1956) introduced the idea of market segmentation, marketers have used personal characteristics to distinguish between different "types" of consumers. By dividing consumers into "sub-populations" and addressing their specific interests through customized product features, brand images, or marketing messages, businesses have been able to substantially increase the effectiveness of their marketing efforts. Early segmentation strategies focused primarily on surface-level demographic characteristics, including age, gender, and nationality, to differentiate consumer groups. Although the use of these surface-level characteristics was a first step toward better understanding and serving consumers' diverse needs and preferences, they ended up lumping very different consumer groups into the same category. Adopting separate marketing strategies for men and women, for example, is a broad segmentation strategy that provides some benefit but still ignores the many differences that exist between people of the same gender. It is thus not surprising that marketers in the 1970s became more interested in psychological factors such as attitudes, values, opinions, and personality, which enable a more detailed view of consumers' most fundamental needs and preferences.

Brand Personality

Underlying the idea of using psychological differences for marketing purposes is a simple yet powerful assumption: people buy products and brands not only for what they can do but also for what they mean (Levy, 1959). Products and brands often carry a symbolic meaning that reaches far beyond their mere functionality, serving as a form of self-expression for the consumer. Taking account of this additional layer of meaning, researchers have used the idea of "brand personality" to describe the human characteristics that are associated with a given brand or product (Aaker, 1997). Coca-Cola, for

example, tends to be perceived as cool, All-American, and real, while Pepsi is described as young, exciting, and hip (Plummer, 1985). As illustrated by this example, a strong brand personality gives consumers something to relate to and helps businesses distinguish their products from those of their competitors. However, although researchers agree that consumers imbue products and brands with characteristics that are similar to those used to describe humans, there is an ongoing debate about whether the dimensions that best summarize these characteristics are the same as those found in humans. The most widely used model of brand personality (Aaker, 1997), for example, proposes the five brand personality dimensions of sincerity, excitement, competence, sophistication and ruggedness, which partly resemble the Big Five personality traits but are not identical.

Self-Congruity in Marketing

Given that consumers attribute various psychological characteristics to different brands and products, a key practical question for businesses is how these symbolic meanings can be used to increase marketing effectiveness. Years of cross-disciplinary research on this question have yielded a very consistent answer: Consumers favor products and brands that match their own personality characteristics (e.g. Aaker, 1999; Aguirre-Rodriguez, Bosnjak, & Sirgy, 2012; Sirgy, 1985). For example, an extroverted consumer is likely to prefer products and brands that are perceived to be sociable, exciting, or stimulating. Known variously as "the self-congruity effect," "self-schema matching," or "self-image congruence," this phenomenon has been explained by the fact that purchasing and possessing self-congruent products and brands helps individuals to maintain and enhance a positive self-concept. Purchasing oil paintings or a book on surrealism, for example, helps an artistic person to express and reinforce her self-concept of being a "creative and open-minded individual." The self-congruity effect has been linked to numerous desirable consumption outcomes such as favorable brand attitudes and purchase intentions, product choice, customer satisfaction, brand loyalty, and life satisfaction.

Message-Person Congruence

Following the logic of the self-congruity effect, studies have also shown that consumers respond more favorably to persuasive advertisements that are aligned with their personal characteristics ("message-person congruence"). For instance, persuasive messages can be framed in terms of gaining a potential reward or preventing a potential loss (e.g. "buy this product to be more popular" vs. "buy this product to avoid being alone"). Such message framings tend to be most effective when they are congruent with an individual's habitual focus on pursuing rewards or preventing losses, respectively (Cesario, Grant, & Higgins, 2004). Similar benefits have been observed when framing persuasive messages so that they are congruent with the Big Five personality trait profiles of the target audience (e.g. Hirsh, Kang, & Bodenhausen, 2012; Wheeler, Petty, & Bizer, 2005). An extroverted consumer is thus more likely to take interest in a relatively neutral product (e.g. a cell phone or a perfume) if the marketing messages used to promote it imply sociable, exciting, or stimulating

characteristics (e.g. highlighting "excitement" or "being in the spotlight" as resulting from product purchase). It has been suggested that the positive effects of personality-matched communications derive from the feelings of "rightness" or "fit" experienced by consumers when decoding the messages. These feelings, in turn, lead to a more positive evaluation of the message content and ultimately in more favorable behaviors.

Personality and Digital Marketing

Insights about the benefits of self-congruity and message-person congruence have been used by marketing professionals to create products, brands, and advertising messages that reflect the characteristics of their desired consumer audiences. However, the practical ability to target consumers on the basis of their psychological profiles has been limited by the reliance on questionnaire-based self-assessments of psychological traits. Although researchers can easily gather such assessments in the laboratory, obtaining them from consumers in the real world has been more of a challenge. With the steady growth of online commerce and the wealth of information on consumers that comes with it, however, this could change. Researchers have recently found that an individual's Big Five personality profile can be reconstructed using information gained from online sources, including personal websites (e.g. Marcus, Machilek, & Schütz, 2006), Facebook or Twitter profiles (e.g. Golbeck, Robles, Edmondson, & Turner, 2011; Kosinski, Stillwell, & Graepel, 2013), and natural language use (e.g. Schwartz et al., 2013). Compiling these digital footprints makes it possible to estimate an individual's personality profile without administering any personality questionnaires. Knowing that liking "Lady Gaga" is related to high extroversion, for example, would allow marketers to identify and target "extroverted audiences" by examining recent search queries on Google, songs listened to on Spotify, or preferences listed on Facebook.

Support for the effectiveness of this technique in real-life digital advertising comes from an experimental study demonstrating that personality-based targeting using computer-estimated personality profiles indeed results in higher click-through rates, conversion rates, and return-on-investment (Matz, Chan, Popov, Stillwell, & Kosinski, 2014). Consumers who were identified as extroverted showed a preference for extroverted products and advertising messages, while consumers identified as introverted tended to favor introverted products and messages. Modeling consumer personality profiles based on the content of Twitter posts has similarly been found to improve the performance of online retailers' product recommendation systems by enabling personality-tailored suggestions (Adamopoulos & Todri, 2015).

While the use of digital footprints to estimate consumer personality profiles enables new forms of market segmentation and message tailoring, it still only constitutes a first step in the potential of digital marketing efforts to become more personalized and effective. Having direct access to consumers' personal Facebook profiles or search queries, for example, makes it possible to narrow down segmentation approaches to the level of the individual, where each consumer constitutes an idiosyncratic "segment" in its own right. Flexible modeling of psychological characteristics at the individual level could advance personalized marketing beyond the exclusive use of static personality traits to also include dynamic states such as consumers' current moods or emotions.

Ethics of Personality and Marketing

Taken together, the ability to estimate psychological characteristics without requiring consumers to complete any self-report questionnaires provides novel opportunities for implementing the well-established research on personality and marketing in the real world. However, it also raises ethical questions about the appropriateness of using information about users' personal characteristics without their consent. From a consumer's perspective, these questions are relevant to concerns about personal control, self-determination, and privacy. Considering that businesses rely on consumers' trust and loyalty, concerns about privacy breaches can, in turn, present a reputational risk for businesses. It should therefore be of the utmost importance that researchers and businesses integrate personality-based marketing in a responsible and transparent way that makes consumers part of, rather than simply the object of, marketing customization. For example, businesses could help consumers better understand their targeting mechanisms (e.g. "we have shown you this bungee jumping advertisement because we believe that you are an extroverted person") and even invite them to actively change their predicted profiles in case they disagree with the predictions. Such an approach helps businesses to maintain users' trust by establishing a mutual agreement of "giving and taking" that is beneficial for both sides.

Personality, Interests, and Careers

Lisa M. Larson and Matthew T. Seipel

Iowa State University

Overview

> *We inherit dispositions, not destinies. Life 'vocational' outcomes are consequences of lifetimes of behavior choices. The choices are guided by our dispositional tendencies and the tendencies find expression within environmental opportunities that we actively create.*

(Rose, 1995, p. 648)

In the above quote, Rose perfectly captures the intersection of work and individual differences or "dispositional tendencies." Paid work for many people is their occupation or career while for others paid work is a job or series of jobs. Career is differentiated from a *job* in that most careers are associated with personal meaning beyond earning an income. Most people pursue one or more careers over the course of their lifetime, and this pursuit is influenced by individual differences.

Two critical individual differences are interests and personality; both are stable across the life span. Interests are people's preferences for pursuing certain activities and avoiding other activities. Personality is one's characteristic pattern of thinking, feeling, and behaving. Interests and personality independently and combined have been shown to predict educational and career outcomes. Scholarship has helped discern the nature of their relationship, yet more research is needed to understand the extent to which they influence people's educational and career paths.

History and Intellectual Context

The individual difference tradition, which emerged around the start of the twentieth century, has been important to the study of careers since the inception of vocational psychology. It emphasized that people's traits can be measured and described as falling

along a normal distribution. A person's uniqueness is defined as the extent to which her/his score on that trait is more than one standard deviation from the "average" person's score. When looking at several traits, each person can be described as unique in relation to how they scored relative to others (e.g. she is extraverted, interested in enterprising activities, and uninterested in investigative activities). Around the same time, the United States was adjusting to its transition from being a largely agricultural to a manufacturing society. To help young men find suitable employment, Frank Parsons, an educator and social reformer, pioneered the vocational guidance movement and promulgated the concept of person-environment (P-E) fit, which proposes that people will be most satisfied in work that is congruent with their skills. Individual differences and P-E fit were critical to service member testing and placement during both world wars, and they also were a major impetus behind the proliferation of career development theories in the 1950s. They remain a vital force in the field, evidenced by the inclusion of a "Personality, Interests, and Careers" chapter in this volume.

Theoretical Underpinnings

The most influential theory of individual differences and career development has been John Holland's P-E fit theory. Originated in the 1950s and revised in 1997, it expanded on Parsons' concept of matching jobs with individuals' skills and posited that a good match between the individual's interests and the work environment is likely to result in better career outcomes. Holland articulated six interest types: realistic (mechanical, practical, working with one's hands, being outdoors), investigative (scientific, analytic, problem-solving), artistic (creative, musical, originator), social (serving/helping others), enterprising (persuading/managing others), and conventional (organizing/working with data/numbers). These interests are commonly referred to by the acronym RIASEC and often measured with the well-known Strong Interest Inventory. Holland also assumed work environments could be described as some combination of those six domains (e.g. farming or engineering would be considered realistic environments). Holland's theory defined P-E fit as congruence; congruence is often measured by assigning a RIASEC code to operationalize a person's interest (e.g. RIS meaning the top three interests for that person are realistic, then investigative, then social) and a similar strategy to label an occupation. Congruence is thought to predict satisfaction, choice, and performance.

Another widely known vocational theory is Social Cognitive Career Theory (SCCT), developed by Robert Lent, Steven Brown, and Gail Hackett in 1994. Adapted from Albert Bandura's social cognitive theory, SCCT emphasizes the central role of vocational self-efficacy across the six RIASEC domains in influencing academic performance, career choice, and career interests. Vocational self-efficacy can be defined as people's confidence to competently execute a task or be effective in an occupation. Thus, SCCT postulates that people with higher domain-specific vocational self-efficacy will be more likely to excel academically in that domain, be interested in pursuing that domain, and choose that domain as an academic major and career. Vocational interest in this model is seen as more determined by vocational self-efficacy although there is evidence to support that the effect is bidirectional. Personality in this model is considered as influencing educational and career

outcomes through vocational self-efficacy. In a large meta-analysis, Sheu and colleagues (2010) confirmed domain-specific vocational self-efficacy as a direct predictor of choice goals, and they also found that self-efficacy relates indirectly to choice goals via vocational interest.

Interests and Career

Interests are the most frequently assessed construct in career counseling. Interests typically begin to develop in early childhood and stabilize as individuals enter adulthood. Rather than forming a hexagon, the structure of Holland's six interest types seem to be circular in nature. This circular structure has been shown to apply across gender and most US racial and ethnic minority groups but may not fit well with international samples. Holland's assertion that congruence or P-E fit, measured as a three-point Holland code for the person and the environment, would predict job satisfaction has received nominal support. However, vocational interest research using the Strong Interest Inventory has overwhelmingly showed that people across the lifespan seek out vocational environments consistent with their vocational interests, stay longer in those careers, and are typically more satisfied in those careers. Moreover, there is evidence that when people change jobs, they choose environments more congruent with their interests. We also know that interests and self-efficacy across the RIASEC can substantially differentiate college students' level of educational aspirations.

Beyond Holland's theory, vocational interests have long been identified as more specific than the six RIASEC interests. For example, investigative interests include mathematics and science interests. Across multiple studies, specific interests can accurately differentiate among families of academic major and occupations much better than the six RIASEC domains alone (e.g. Gasser, Larson, & Borgen, 2007). Moreover, when domain-specific self-efficacy (e.g. mathematics self-efficacy, engineering self-efficacy) as a set of predictors is added to specific interests, the differentiation of academic majors and/or occupations across diverse fields and populations is even more impressive. In sum, vocational interests are potent predictors of educational aspirations, academic major choice, and career choice.

Personality and Career

Two personality models that have received the most attention in vocational psychology are the Five Factor Model ("Big Five") and the Three Factor Model ("Big Three"). The Big Five consists of five dimensions: neuroticism (sometimes referred to as "emotional stability"), extraversion, openness to experience, agreeableness, and conscientiousness. The Big Three identifies three higher-order dimensions: positive emotional temperament, negative emotional temperament, and constraint, which captures behavioral regulation. The Big Three is further divided into 11 primary, lower-order traits.

Personality traits have been mostly examined in the world of work (see Judge, Heller, & Mount, 2002, and Barrick & Mount, 1991, for excellent meta-analyses). More frequent job search behaviors over a longer duration have been modestly correlated with extraversion,

openness, and conscientiousness. Number of job offers received has been modestly correlated with extraversion, openness, and agreeableness. Modest effect sizes have been found for the relation of neuroticism, extraversion, and conscientiousness with job satisfaction. Positive emotional temperament also has been positively associated with job satisfaction and negatively associated with job turnover. Conversely, negative emotional temperament has been negatively associated with job satisfaction and positively associated with job turnover.

A critical career-related outcome is job performance. Job performance is often described in broad terms (global job performance) or in terms of specific facets of the job (e.g. instrumental and contextual job performance). Conscientiousness is the only Big Five personality trait correlated across global job performance and all subscales, including organizational citizenship behavior. Extraversion and openness have been correlated with the specific domain of training proficiency.

Turning to college students, in separate studies, the Big Five and the lower-order primary traits of the Big Three did add significantly to the discrimination of families of academic majors. Finally, the Big Five discriminated among different levels of educational aspirations. The contribution of personality traits to the prediction of academic major or educational aspirations is modest in comparison to the contribution of interest and/or self-efficacy. In summary, personality traits from the focal models have been mostly correlated with career outcomes in the world of work.

A Framework for Integrating Vocational Interests, Personality, and Career

Multiple meta-analyses (e.g. Larson, Rottinghaus, & Borgen, 2002) have found significant overlap between personality and interests, suggesting related yet distinct traits. Of the 30 possible relationships between the six Holland interest types and the Big Five traits, at least six appear to be meaningful across gender. Investigative and artistic interests overlap with openness to experience. Social interests overlap with extraversion and agreeableness. Enterprising interests overlap with extraversion. Conventional interests overlap with conscientiousness only for men completing the Strong Interest Inventory. More precise interest-personality linkages were shown with Holland's RIASEC and the lower-order primary traits of the Big Three. In this meta-analysis, enterprising and social interests were more clearly differentiated from each other with enterprising interests being positively related to social potency (forceful and decisive), while social interests were positively related to traditionalism (social conservative) and negatively related to aggression (victimizer). Moreover, realistic interests and investigative interests showed overlap with the inverse of harm-avoidance (chooses safe and boring over danger), and investigative interests overlapped with achievement (works hard). Finally, artistic interest overlapped with absorption (entranced by evocative sights and sounds), and social and enterprising interests overlapped with social closeness (sociability).

In their seminal article, Ackerman & Heggestad (1997) presented meta-analytic evidence that the six interest domains, the Big Five, the lower-order traits of the Big Three, and different domains of cognitive ability could be integrated into four *trait complexes*.

They include science/math, intellectual/cultural, social, and clerical/conventional. The trait complexes have been found accurate in retrospectively differentiating adults' college majors.

Future Directions

A primary task for scholars of individual differences and vocational psychology is to generate new knowledge. Additionally, this area will be served by the integration of existing knowledge; this should come in the form of meta-analyses and conceptual reviews. Knowledge then needs to be disseminated to a wider audience. Necessary populations include vocational counselors and other practitioners in the field, undergraduate students, and scholars in related disciplines. Relatedly, individual difference and vocational psychology scholars must engage in interdisciplinary sharing and collaboration outside of their niche areas. Fruitful work will come from collaboration with psychological areas like industrial/organizational, clinical, social, and developmental. Lastly, the field must continue to stay in touch with the multicultural zeitgeist. Traditional lines of inquiry have neglected diverse, nondominant groups; the field has an ethical obligation to correct this disparity, promote social justice, and keep pace with a world of work that will continue to become increasingly global and cross-cultural.

Personality and Counterproductive Work Behavior

Tabatha Thibault and E. Kevin Kelloway

Saint Mary's University

Workplace deviance, also known as counterproductive work behavior (CWB), antisocial workplace behavior, and workplace aggression, is defined as voluntary behavior that harms (or is intended to harm) the organization (CWB-O, e.g. theft, absenteeism, sabotage) or its members (CWB-I, e.g. violence, incivility, gossip; Bennett & Robinson, 2000). Although workplace deviance may be in response to organizational variables such as perceived injustice, a large body of research has shown that individuals may be predisposed to engage in these types of behaviors.

The majority of this research examining individual antecedents of workplace deviance has focused on the Big Five personality variables: conscientiousness (organized, thoughtful, and responsible), agreeableness (considerate, trusting, and kind), neuroticism (anxious, insecure, and worrying; versus emotional stability), extraversion (sociable, assertive, and outgoing), and openness to experience (imaginative, original, and curious). A meta-analysis conducted by Hastings and O'Neill (2009) found that the Big Five personality traits explained 35% of the variance in CWB.

Within the Big Five, workplace deviance is most consistently and negatively related to, or predicted by, conscientiousness and agreeableness. A meta-analysis by Grijalva and Newman (2015) found correlations of -0.44 for agreeableness, and -0.35 for conscientiousness with measures of deviance. Conscientiousness is more strongly associated with CWB-O while agreeableness is more strongly associated with CWB-I (e.g. Berry, Ones, & Sackett, 2007). Neuroticism has also been positively linked to workplace deviance (Grijalva & Newman, 2015). Marcus, Lee, and Ashton (2007) found that emotional stability (the reverse of neuroticism) was negatively correlated with CWB. Additionally, Garcia, Wang, Lu, Kiazad, and Restubog (2015) found that neuroticism predicted CWB based on archival data 18 months later. Some studies have found a weak negative relationship between deviance and extraversion (e.g. Mount, Ilies, & Johnson, 2006). However, meta-analyses and other studies find no link (Berry et al., 2007; Marcus et al., 2007) or even a positive link (Lee, Ashton, & Shin, 2005) between CWB and extraversion. Similar results were found

when examining the CWB-openness relationship (e.g. Berry et al., 2007; Judge, LePine, & Rich, 2006; Mount et al., 2006).

Narrower facets of the Big Five traits have also been linked to workplace deviance. Hastings and O'Neill (2009) found that, together, a facet of each overall trait explained 33% of the variance in CWB. Specifically, excitement seeking (extraversion facet) and anger (neuroticism facet) positively predicted CWB while cooperation (agreeableness facet), dutifulness (conscientiousness facet), and emotionality (openness facet) negatively predicted CWB (Hastings & O'Neill, 2009). Similarly, meta-analytic results show that achievement (hard working, focused, and ambitious; conscientiousness facet), nondelinquency (follows laws, rules, and norms; conscientiousness facet), and cooperation (trusting, compliant, and noncritical; agreeableness facet) all have a negative relationship with counterproductive behavior while attention seeking (loud, entertaining, and boastful; extraversion facet) has a positive relationship with counterproductive behavior (Drasgow et al., 2012). Some research has also explored the interaction between personality traits on workplace deviance (Burns, Morris, & Wright, 2014). Dutifulness (the interaction or combination of conscientiousness and agreeableness), and purposefulness (the interaction between conscientiousness and emotional stability) both negatively predicted CWB above and beyond the individual traits (Burns et al., 2014).

Since the development of the HEXACO model, personality researchers have started exploring a sixth trait, honesty-humility (H-H; Lee & Ashton, 2004). Those with this trait are sincere, cooperative and fair, and lack greed and conceit. There is also a sub-category of the trait called trait fairness, defined as an avoidance of cheating, lying, or stealing. Honesty-humility negatively predicted overall CWB, CWB-I, and CWB-O (O'Neill, Lewis, & Carswell, 2011). Similarly, trait fairness also negatively predicted CWB, CWB-I, and CWB-O (O'Neill et al., 2011). Furthermore, there is evidence that both honesty-humility and trait fairness predicted CWB above and beyond conscientiousness, agreeableness, and neuroticism (O'Neill et al., 2011).

Counterproductive work behavior has also been linked to the dark triad, a constellation of narcissism, Machiavellianism, and psychopathy. Those high in narcissism hold a grandiose sense of self-importance, a tendency to feel entitled, and are often arrogant and exploitative. Those high in Machiavellianism have a tendency to use manipulative tactics to get their way, lie frequently, and take revenge against others. Finally, those high in psychopathy lack empathy and social regulatory mechanisms, tend to be impulsive, and lack guilt or remorse. A meta-analysis found that, together, the dark triad explained 28% of the variance in CWB (O'Boyle, Forsyth, Banks, & McDaniel, 2012).

Of the three dark triad traits, narcissism has the strongest relationship with workplace deviance (O'Boyle et al., 2012). In fact, a meta-analysis found that narcissism explained an extra 9.2% of the variance in CWB above and beyond the Big Five traits (Grijalva & Newman, 2015). Facets of narcissism have also been linked to workplace deviance (Grijalva & Newman, 2015). Specifically, leadership/authority (L/A; wanting to have authority over others) was negatively associated with overall CWB and CWB-O, and entitlement/exploitativeness (E/E; feelings of entitlement and manipulative behavior) was positively associated with overall CWB, CWB-I and CWB-O (Grijalva & Newman, 2015). Machiavellianism is also positive associated with both CWB-I and CWB-O although psychopathy appears to be unrelated to both forms of workplace deviance.

Researchers have also looked at specific personality traits as predictors of workplace deviance. Trait anger refers to a predisposition to experience anger and respond with hostility. Trait anger is positively related to various measures of workplace deviance like overall CWB, CWB-I and CWB-O, as well as with aggression directed toward both individuals and the organization (Hershcovis et al., 2007). Those high in negative affectivity tend to experience general distress and aversive mood states such as anger and nervousness. Negative affectivity has been positively linked to CWB, interpersonal and organizational aggression, overall workplace aggression, and organizational retaliatory behavior.

A small number of workplace deviance studies have examined other personality variables. For instance, Douglas and Martinko (2001) found that workplace aggression is negatively correlated with self-control and positively correlated with a hostile attributional style. Individuals with a hostile attribution bias are also more likely to exhibit CWBs (CWB-O, CWB-I, and relational aggression). Having an external locus of control (believing that others control outcomes) is positively associated with engaging in deviant behaviors such as sabotage. Finally, overall CWB was positively correlated with humorousness, manipulativeness, risk taking, and seductiveness, and was negatively correlated with integrity, and religiosity. These six traits significantly predicted CWBs above and beyond the Big Five traits (O'Neill & Hastings, 2011).

Extant research has identified numerous personality traits that seem to be empirically related to organizational deviance. How these traits interact with each other and with organizational conditions remains a potentially fruitful avenue of research. Understanding the role that personality plays in predicting workplace deviance may provide both greater conceptual understanding of counterproductive behaviors and identify avenues for potential organizational interventions. The identification of personality predictors of workplace deviance may, for example, provide a basis for employee selection or provide the basis for identifying individuals for early intervention.

Friedman, Howard

Leslie R. Martin

La Sierra University

Introduction

Howard S. Friedman is a pioneering scientist who has shifted our thinking about personality and health in meaningful ways. After receiving his A.B., magna cum laude, at Yale University in 1972 he went on to complete a Ph.D. in social psychology, mentored by Robert Rosenthal, at Harvard University in 1976. His doctoral work focused on the role that facial expression of emotion plays in verbal communication and throughout the late 1970s and early 1980s a primary focus of his efforts was on nonverbal expressivity and skill. This work included study of the process of emotional contagion and the ways in which nonverbal skills might be harnessed to improve the communication between physicians and their patients. Key changes in training models for medical students can be traced back to some of these findings and ideas, and his influence is also reflected in empirical trajectories in the area of medical interactions. He also codeveloped the widely used *Affective Communication Test* (Friedman et al., 1980), which has become an important tool for emotional expressivity researchers and which continues to have a major influence on viral marketing research (using emotional elements of social networks to produce exponential increases in product or message awareness). Thus, although trained as a social psychologist, Friedman's interests were always heavily health-related – he was a health psychologist when the label and formal training in the field were uncommon. He was also a genuine teacher-scholar.

From the mid-70s, Friedman had been dedicated to applied psychological research, particularly aspects related to health; in the early 1980s he began to place more emphasis on education in health psychology. He worked to develop one of the first model courses in health psychology (NSF-funded), and in 1983 he participated in the Arden House National Conference on Education and Training in Health Psychology. He co-wrote the first (authored) textbook in health psychology, and he chaired or advised on a series of health psychology training conferences throughout the 1980s for graduate students, postdoctoral students, and faculty in health psychology. A consummate mentor, Friedman's honors

include the University of California's Distinguished Teaching Award (1995), the Western Psychological Association's Outstanding Teaching Award (2000), and the title of distinguished professor at the University of California, Riverside (2000). Friedman's most important contributions, however, have been made at the intersection of personality and health psychology.

Beginning in the late 1980s, Friedman's research increasingly emphasized personality and psychosocial precursors of physical health outcomes, and the interactive pathways by which they influence health. Two especially influential early articles were meta-analyses – one identified a generic "disease-prone" personality (Friedman & Booth-Kewley, 1987) and the other quantitatively reviewed the psychological predictors of heart disease (Booth-Kewley & Friedman, 1987). These articles demonstrated that multiple health and psychosocial factors must be considered simultaneously, rather than focusing on individual components and diseases, and they fueled a great deal of interest in (and new research on) the interface of psychosocial factors and health.

Soon thereafter followed two edited books, *Personality and Health* (Friedman, 1990) and *Hostility, Coping, and Health* (1992) both of which have been used extensively by professionals and graduate students interested in the processes by which personality and psychosocial elements interact with biological features to create unique outcomes. Although the work cited here has been influential in the scientific community, Friedman has always been committed to bringing empirical findings to lay audiences. Toward this end, he has conducted hundreds of interviews with members of the scientific and popular press (including *The Washington Post*, *The New York Times*, *Science News*, PBS, BBC, CBS, and ABC) on a variety of health-related topics; and his popular 1991 book, *The Self-Healing Personality: Why Some People Achieve Health and Others Succumb to Illness,* has been reprinted six times (including French, German, Romanian, and Polish). This term, the "self-healing personality," is now widely adopted.

In 1990, Friedman began a new and innovative research program, tapping the vast archives of Terman's Life-Cycle Study (begun with 1,528 10- to 11-year-olds in 1921) to longitudinally and prospectively study the integration of personality, emotion, and health. By taking a social science approach to questions about what promotes longevity and health, he began to formulate a life-pathways approach to understanding the complex interactions that define our lives and health. This technique approximates what is now called life-course epidemiology. As the principal investigator on this project, Friedman put together a top-notch, interdisciplinary team, and a successful strategy – this team has published articles on precursors, pathways, and interactions among psychosocial and physical health variables (including personality, parental divorce, sexuality, mental health; marital stability, family relations, and bereavement), as well as numerous book chapters.

The first, and still most heavily cited of the empirical articles was one that appeared in the *Journal of Personality and Social Psychology* entitled "Does Childhood Personality Predict Longevity?" (Friedman et al., 1993). The major finding here was that childhood personality, especially the trait of conscientiousness, was predictive of mortality risk across the life-span. This paper's publication inspired a flurry of new research into personality and health and the importance of conscientiousness as a key psychosocial predictor has been replicated and confirmed (e.g. Bogg & Roberts, 2004; Kern & Friedman, 2008). The published findings from this project were integrated into a book for lay audiences, released

in 2011, titled *The Longevity Project – Surprising Discoveries for Health and Long Life from the Landmark Eight-Decade Study* (Friedman & Martin, 2011); it has since been reissued in multiple languages.

The findings from this study provided fodder for additional theory-building, and Friedman's more recent work includes pieces that take on more complex integrations and address large-scale understandings of personality, health, and well-being (e.g. Friedman, Kern, & Reynolds, 2010; Friedman & Kern, 2014). For example, his conceptualizations of the driving forces behind our actions, choices, and experiences as "dynamisms, mechanisms, and tropisms" argues for a change in the way we think about stress and coping, and that the stressors we encounter are not random, but in fact are set in motion by biological predispositions and early life experiences (Friedman, 2000). Similarly, he cautions policy makers against making broad recommendations that fail to take into account individual personalities and the life paths on which people are already traveling.

Furnham, Adrian Frank

Konstantinos V. Petrides

University College London

Adrian Frank Furnham is currently adjunct professor at the BI Norwegian Business School in Oslo. Previously he was professor of psychology at University College London (1992–2018), visiting professor at the University of Hong Kong's Business School (1995–1997), and visiting professor at the Henley Management College (1999–2001). He is also a distinguished broadcaster, motivational speaker, and consultant to major international companies on leadership, management, and organizational behavior. His research falls within the domain of personality and social psychology, broadly defined.

For many years, Furnham has ranked among the world's most prolific psychologists. He has published extensively on topics as diverse as cross-cultural psychology, economic psychology, lay theories, leadership and management, personality disorders, psychology of money, self-estimates of intelligence, and the Protestant work ethic, which his lifestyle exemplifies.

Personal Details

Furnham was born on February 3, 1953, in Port Shepstone, South Africa (SA) to British parents Leslie Frank Furnham and Lorna Audrey (née Cartwright). Following his primary and secondary education in Pietermaritzburg (KwaZulu-Natal, SA), he went on to obtain, initially (in 1973), a B.A. honors and, subsequently (in 1975), an M.A. (by research) in History, Psychology, and Theology. In 1976, he was awarded, by the London School of Economics, an M.Sc. with distinction in Economics, and by the University of Strathclyde, an M.Sc. in Psychology (by research). He then went on to pursue a PhD at the University of Oxford under the supervision of Michael Argyle on the topic of person-situation interaction, which he was awarded in 1981. This was the first of three doctorate degrees, the other two conferred on the basis of selected publications, from the University of London in 1991 (D.Sc.) and from the University of KwaZulu-Natal in 1997 (D.Litt.).

In 1981, Furnham was appointed lecturer in the Department of Psychology at University College London, with promotions to reader in Psychology in 1988, and to professor of psychology in 1992. He is also honorary professor at the University of KwaZulu-Natal (2015–) and adjunct professor at the Norwegian Business School (2009–). Previously, he held visiting professorships at the School of Business in the University of Hong Kong (1995–1997) and at Henley Management College (1999–2001).

Since 1990, he has been married to Dr. Alison Green, whom he met during his doctoral days at Oxford. They live in central London together with their son, Benedict.

Research Topics and Key Contributions

Furnham's research contributions are so diverse and extensive as to defy classification and straightforward summary. Perhaps a valid integrative influence may be found in the writings and general scientific approach of Hans J. Eysenck (cf., hypothetico-deductive empiricism), whom Furnham regards as one of his scientific heroes. The sheer size and magnitude of his outputs make it difficult to identify Furnham's most important contribution to the science of psychology, all the more so because said outputs have not been cast within the framework of a readily identifiable theory. Having worked in almost every area of psychology, he has stood firmly against the strong trend toward early and rigorous over specialization that is becoming characteristic of the discipline. Indeed, it is rather difficult to disagree with his observation that no serious behavioral question is the exclusive purview of one branch of psychology.

In Furnham's own opinion (Furnham, 2017), his research on culture shock (which has yielded what still remains his best cited book), on the psychology of alternative medicine, and on the psychology of money represents his best work, to which I would personally add his contributions to the literature on the Protestant work ethic. However, it is his voluminous work (over 50 publications to date) on self-estimates of intelligence, which has been most influential and which I have attempted to summarize below.

People who are asked to estimate their IQ tend to provide estimates up to one standard deviation (15 IQ points) above average, with male IQ self-estimates consistently higher (about 5–15 IQ points) than female self-estimates. Extending this research into multiple intelligences revealed deep-seated stereotypical judgments, with males estimating their numerical and mathematical intelligence higher than females, but females estimating their emotional intelligence higher than males. Fascinatingly, these differences seem to be cross-culturally stable and intergenerational, with grandfathers rated as more intelligent than grandmothers, fathers more intelligent than mothers, but mothers more emotionally intelligent than fathers. Such has been the influence and significance of this work that it seems to have spurred a new research area, complete with methodological, cross-cultural, and meta-analytic studies.

Working Style and Attitudes to Publication

Furnham describes himself as a well-adapted workaholic. A morning person, he starts work about 6 a.m. and finishes around 5 p.m., often for an after-dinner speech or spot of

management consultancy or to write a newspaper column. That is during periods when he is actually in London because one will regularly find him globetrotting on various assignments and projects.

Behind his productivity lies the example of his scientific role-models, most of whom were extraordinarily prolific. Work is his only real passion, which he sees as "more fun than fun" and which is why he has been spotted in the office at weekends or scribbling at the beach on holidays. His only publishing strategy, if it may be called that, is to follow his heart and work on topics that he finds stimulating. At any one time, he could be working on a dozen papers and three books on different topics.

Furnham is nonconformist with respect to publication outlets. He believes a good journal is one that is widely read and keeps up to date, and points out that enjoyable and pioneering journals do not necessarily have high impact factors. Furnham has published in hundreds of journals and is one of the world's most highly cited psychologists without ever having to bow to the obsessionality of ostensibly elite journals that place inordinate emphasis on conservativism and extra-scientific minutiae to the detriment of creativity, originality, and innovativeness. He often recounts how Argyle once said to him, "Why spend all the effort on writing a paper for *Psychological Bulletin* when it takes the same effort to write a book? Why not write a book and you can actually make some money as well!"

His speedy style of work and lack of reverence for the increasingly pernickety publishing rules and regulations may be considered anti-normative in modern-day academia. In any case, they have frequently pitched him against ideological reviewers, who reject all papers that do not fit their particular theoretical or statistical agenda, and fetishistic editors, who refuse to even send submissions out for peer review unless they have been formatted according to the latest edition of the APA publication manual.

Tips to PhD Students and Young Researchers

According to Furnham, learning to cope with rejection is a sine qua non for a successful career in academia. Having been exposed to over 5,000 review commentaries, he is well aware of the likelihood of experiencing vitriolic rejection by bitter peers with an ax to grind. He has seen many a researcher become disillusioned and broken by negative reviews. Interestingly, Furnham, who has collaborated with hundreds of co-authors from widely different ages, backgrounds, and disciplines, has noticed that women and younger researchers are disproportionately likely to be put off by venomous rejections, which may have something to do with the continuing under representation of women in professorial posts.

Faced with rejection, Furnham's advice is to set the reviewers' comments aside for a day or two and revisit them with a cool head and a view to determining whether they establish any theoretically or methodologically irrecoverable errors. If not, the manuscript should be swiftly revised and resubmitted. He also advises authors to avoid his, temperamentally inflicted, casual attitude to journal selection that has been the source of much frustration over the years. Rather, an author should always target outlets carefully, after reading their past four or five issues, and meticulously catering to their particular house style and audience, a blatant case of "do as I say, not as I do," if ever there was one!

Furnham says that budding academics need to do four things to become successful. First, early on, they should publish a critical, systematic, literature review, coupled with a meta-analysis on a hot topic in order to ensure a steady stream of citations for long periods of time. Second, they should design a psychological test because such tests can become very popular and bring recognition. Third, they should get hold of, or create and maintain, a longitudinal sample that can provide waves of increasingly ambitious publications for the rest of their career. Fourth, and last, they should cultivate the ability to sense new trends and move swiftly into nascent topics that have the potential to develop into research fields in their own right.

Fellowships, Awards, and Esteem Indicators

Furnham is Fellow of the British Psychological Society and of the Leadership Trust, Senior Fellow at the Singapore Civil Service College, Academician of the Learned Society of the Social Sciences, and elected past president of the International Society for the Study of Individual Differences. He has served on the editorial board of at least a dozen international journals and as ad hoc reviewer for numerous others as well as for prestigious research grant awarding bodies.

Consistently ranked among the most productive psychologists in the world, Furnham has published well over 1,200 peer-reviewed articles and 80 books. In that respect, it is perhaps worth noting that extraordinary productivity has been identified as a characteristic of genius (Simonton, 1988). Over the years, Furnham has received several honorable citations for his productivity and has regularly featured in lists of highly cited and prominent psychologists. Most recently, he was included in an international list of 200 eminent psychologists in the modern (post-World War II) era, based on citation impact, textbook mentions, and major scientific awards (Diener, Oishi, & Park, 2014).

Beyond academia, Furnham is the founding director of a psychological consultancy, Applied Behavioural Research Associates, which has been operating successfully since 1985 and whose clients have included very major organizations, such as British Airways, the British Army, Credit Suisse, Goldman Sachs, KPMG, Specsavers, and the Ritz hotel, among many others. He has had columns in national newspapers, such as the *Financial Times*, *The Sunday Times*, and *The Daily Telegraph*, and is a regular contributor to national and international radio and television programs, such as those of the BBC, ITV, and CNN.

Furnham is that rare specimen of academic who has successfully overcome the scientist versus practitioner divide that is so evident in all areas of applied psychology. As a researcher, he has avoided the pursuit of academically respectable, but practically futile, topics; as a practitioner, he has resisted becoming outdated and reliant on golden-oldie theories; and as a broadcaster he has persistently challenged conventionalism and pusillanimity. Since 1997, he has maintained an entry in A&C Black's *Who's Who*, where important updates about his life and contributions will continue to be listed for many years to come.

Hogan, Robert

Robert B. Kaiser

Kaiser Leadership Solutions

Every now and then a scientific discipline moves forward. You can usually trace the advance to an iconoclast whose bold ideas and relentless commitment to them eventually prevail against the headwinds of orthodoxy. The personality theorist, Robert (Bob) Hogan, is one such iconoclast.

Today personality is everywhere – beyond social psychology and organizational psychology to most subdisciplines, and even in other disciplines like economics, history, and political science. Personality assessment is commonplace in the corporate world – from employee recruitment and selection, to training and development, team building, and leadership succession. This is largely thanks to the clear thinking, hard work, and phenomenal perseverance of Bob Hogan. Before his crusade, the conventional wisdom in psychology was that personality didn't much matter (and probably didn't even exist) because situational forces determined behavior (Mischel, 1968). To understand how a poor kid from rural California revived and redefined the field launched by his intellectual hero, Sigmund Freud, you need to understand his story. For who Hogan is *is* an inextricable part of how and what he thinks.

Beginnings

Hogan was born in 1937, the first child of a working-class family that had moved to southern California during the Great Depression. His parents instilled a strong work ethic and he had his first job at the age of 13. Young Hogan was bright and curious, but found school tedious and boring; he also struggled with authority relations and was frequently in trouble for his disruptive influence in the classroom. Outside school, he was fascinated by the study of animals – particularly the insects and desert reptiles of California – and by girls. By his own initiative he read a great deal, including Darwin, which sharpened his appreciation for the animal behavior he had been observing, and Freud, which intrigued him with the idea that people did things for reasons of which they were dimly aware but that were a function of underlying erotic preoccupations.

Hogan went on to undergraduate studies in the University of California system but didn't major in psychology because those courses involved the study of lab rats and covered neither evolution nor Freud. He pursued physics, engineering, and philosophy instead, but found them to be frustrating because of their lack of practical certainty. However, they did expose him to the importance of data, mathematical modeling, and existentialism.

Hogan had joined the Naval Reserve Officer's Training Corps to pay for his education, so after completing undergraduate studies he spent three years as an officer at sea. He turned around his gunnery unit, which became the highest performing on the ship, and received a letter of commendation from the Secretary of the Navy. This earned resentment from his fellow officers. They were privileged, middle-class young men and took exception to the way Hogan out performed them by treating the sailors under his command as respected equals. He quarreled with his peers often.

After leaving the Navy in 1963, Hogan took a job as a probation officer in San Bernardino, California. This was a life-changing experience. His boss, a student of Carl Rogers, and other colleagues were kind and committed to helping troubled kids. Hogan's job was to evaluate teenagers who had gotten in trouble with the law. He had no empirically-based guidelines and found his classes on the behavior of lab rats of little help. However, what he did find helpful was a book on abnormal psychology. Hogan concluded that there were few neurotics and even fewer psychotics among the delinquent population he evaluated, but all of them seemed to have a personality disorder.

Graduate Studies

Inspired by his work as a probation officer, Hogan pursued a PhD in personality psychology at the University of California, Berkeley. The Berkeley faculty included many esteemed psychologists such as Jack Block, Richard Lazarus, and Ed Ghiselli but it was the local Institute for Personality Assessment and Research (IPAR) where he felt most at home. The IPAR staff included Harrison Gough, Frank Barron, Donald McKinnon, Ravenna Helson, and other imaginative psychologists dedicated to the empirical study of high-level effectiveness.

A few key events in graduate school proved fateful in shaping Hogan's career. First, the response-set controversy proposed that answers to personality-questionnaire items are based on social desirability. This nearly killed substantive personality research, as researchers began to study the process of item responding instead of the consequences of individual differences. Second, Warren Norman gave a presentation at IPAR on his extensions of Tupes and Christal's (1961) empirical work suggesting the structure of personality measurement could be described with five factors (see Big Five). The model ran contrary to prevailing views but Hogan found the data convincing. Third, Hogan was exposed to Harrison Gough and his practical philosophy of personality measurement. Gough considered classical test theory and its goal for assessment as the estimate of "true scores" to be nonsense; instead, Gough built the *California Psychological Inventory* (see California Psychological Inventory (CPI)) on the idea that the goal of assessment is to predict behavior. Finally, Mischel's (1968) famous attack on personality psychology was published, and it ushered in an era of behaviorism and hostility toward personality. Social psychology and

situational explanations became de rigueur, making it nearly impossible to publish research on individual differences. Hogan's career has largely been motivated by proving that Michel was wrong.

Hogan's dissertation concerned the development of morality. It contrasted the Freudian view, which focused on attitudes toward authority, with the role-theoretical view of George Herbert Mead, which focused on meeting expectations for social interaction. It was an exercise in self-discovery: Hogan has serious authority issues, yet a strong sense of morality. His personal sense of fairness was influenced by the indignities and injustices he experienced growing up poor and in his struggles to reach the middle class. His dissertation study used Gough's approach to measurement to work out the links between psychoanalytic and role theoretic views of morality, and much of his subsequent research has focused on the integration of these two complementary systems.

Personality Theorist

Hogan took his first academic professorship at Johns Hopkins in 1967, and although he received awards for his teaching, he struggled to find top-tier outlets that would publish his research. His first submission to the *Journal of Applied Psychology*, a study showing how personality predicted the performance of police officers, was rejected by the editor who commented, "Everyone knows these tests don't work." In classic Hogan form, he declared war against the critics of personality and fought them on two fronts: by continuing his own research and by creating a reputable outlet for the research of others.

In 1977, he convinced the chairman of the APA's Publications and Communications Board that there was a lot of important personality research but few prestigious outlets in which to publish it. The chairman established a new section in the *Journal of Personality and Social Psychology* focused on personality and appointed Hogan as editor. The move outraged social psychologists, but under his leadership the section quickly became influential and *JPSP* became one of the most successful APA journals. It also made it possible to have a career in personality psychology, and articles by Dan McAdams and Dean Keith Simonton soon became classics in the larger field of psychology.

Hogan's own research has been prolific and highly influential. It can be broadly summarized as involving five initiatives.

First, as an engaging instructor at Johns Hopkins, he involved his students in a project to apply the Five Factor Model. They rejiggered Gough's CPI and determined that a Five Factor scoring key produced stronger empirical results. Out of respect to his former mentor, however, Hogan did not publish the results. Instead, he and his students created a new test based on the Five Factor Model, the *Hopkins Personality Inventory* (later renamed the *Hogan Personality Inventory*, or HPI). In addition to being structured around the latest empirical findings, it was also developed using a normal population of working adults, as opposed to clinical samples, making it ideal for workplace applications.

Second, after Hogan left Hopkins to start and chair an industrial-organizational psychology program at the University of Tulsa in 1981, he focused his efforts on combining Freudian theory and role theory and tested them out using HPI data. He presented this work at the University of Nebraska's revered annual Symposium on Motivation, where he

first introduced his socio-analytic theory (Hogan, 1983). The presentation was grand in its intellectual ambition, using evolutionary theory (see Evolutionary Theory of Personality) to synthesize the best insights from psychoanalysis with the best insights from sociology. The argument boiled human motivation down to biologically based needs to get along, get ahead, and find meaning in life; it set an agenda for personality assessment as quantifying individual differences in these capabilities. The theory also defined the assessment process as a "self-presentation" where test-takers try to create a certain impression, rather than a "self-report" of their underlying traits. The distinction between description (traits) and explanation (motivation) of personality phenomena was also clarified. In a single presentation, Hogan seemed to resolve all the major controversies and criticisms of personality assessment. For instance, when personality-performance relationships are organized and meta-analyzed using socio-analytic theory, the correlations are substantial (Hogan & Holland, 2003).

A third initiative was based on his experience in the Navy. In 1985, Hogan began studying the psychological literature on leadership and was disappointed to find that there was no consensus about the qualities of a "good leader" and that the prevailing view was that "it depends": in the right situation, anyone can be a successful leader. Taking a cue from Piaget, Hogan turned the question upside down: if there are no common qualities associated with successful leadership, what about failed leadership? And by systematically studying examples of failed leadership in the military, government, academics, and especially business, he concluded that leaders typically fail for one or more of a finite set of irritating interpersonal behaviors (e.g. abrasiveness, volatility, arrogance, exploitation). This work led to his formulation of leadership, based on evolutionary theory (Evolutionary Theory of Personality), as the social force needed to influence selfish members of a group to set aside their personal agenda, for some time, and work together to outcompete rival groups (Personality and Leadership). Further, he noted that bad leadership is the norm, largely because people are drawn to leadership positions for selfish reasons (Hogan, Curphy, & Hogan, 1994; Hogan & Kaiser, 2005; Van Vugt, Hogan, & Kaiser, 2008).

The fourth initiative is an offshoot of Hogan's study of failed leadership. Closer examination of the irritating interpersonal tendencies led him and his wife, Joyce, to realize that these qualities were distinct from the dimensions of normal personality measured by the HPI. These tendencies resembled the personality disorders he observed among juvenile delinquents; they had a selfish quality and were used to manipulate others for short-term gains, albeit with long-time costs. The Hogans described these attributes collectively as "the Dark Side" of personality, and they designed the *Hogan Development Survey* (HDS) to measure them (Hogan & Hogan, 2001). The scales on the HDS overlap somewhat with the "Bright Side" dimensions of the Five Factor Model but are conceptualized as extending to the extreme ends of these continua, at which reside rigid and inflexible tendencies to manipulate other people (see also Sub-Clinical Traits in the Workplace for more on the dark side of personality). The Dark Side has been one of the more captivating concepts Hogan has introduced and has been remarkably influential in both research and real-world applications in business.

The fifth initiative has been Hogan's refutation of the accusation that faking renders personality testing invalid. The standard view is that personality-test items are transparent and that test-takers can tell which response is socially desirable, so they provide false

reports of their tendencies by choosing the more desirable responses rather than honestly describing themselves (see Response Styles, Issues of). Hogan's counterargument is that social life is "all faking, all the time." That is, people are born self-interested and the process of socialization, from parenting to schooling and beyond, is about teaching them to suppress their selfish urges and instead behave according to socially acceptable conventions. Viewed this way, the observed variation in personality-test scores represents differences in test-takers' social knowledge and skill, which is valid variance for predicting social performance. Support for his argument is apparent in the fact that there is variability in personality-test scores and that those scores correlate with real-world behavior in meaningful ways (see Personality and Intelligence in Employee Selection for relationships between personality and employee performance). And although experimental manipulations can get people to (slightly) change their test scores, a study of over 5,000 job applicants who took a personality test but were denied employment showed no substantive enhancements in their test scores when offered a second chance six months later (Hogan, Barrett, & Hogan, 2007). In other words, faking may exist in theory but it doesn't in practice.

Summary

Not long ago, applied psychology had no personality. Thanks to the curiosity, creativity, and persistence of one of psychology's most iconoclastic personalities, the subject is now a central concept in applied psychology and beyond. Bob Hogan has thought carefully and fought doggedly for 50 years to prove that personality is real and consequential. Of course, skeptics remain. As Hogan is fond of noting, the great physicist, Nihls Bohr, once observed that no amount of data will convince your academic critics; you have to wait for them to die.

Holland, John

Jo-Ida C. Hansen

University of Minnesota

John Lewis Holland was a theorist, researcher, practitioner, and educator. His graduate training was in psychology but his specialties were interest and career assessment and vocational psychology. Holland was born in 1919 in Omaha, Nebraska. His parents were of English-Irish ancestry. His father immigrated from London to Canada, where he worked as a laborer in the wheat fields. In 1911, Holland's father moved to Omaha and worked dismantling old train cars for the Union Pacific Railroad until he made a substantial career change and became a store window decorator and eventually an ad man for a gift shop, then an ad man in a large furniture store and eventually, formed his own advertising agency. Holland's mother was a teacher before she married his father; her students were primarily immigrant children from Russia, Sweden, and Denmark. Both of Holland's parents had artistic interests; his father was a writer and artist, and his mother played the piano and had a great appreciation for music. Holland had two brothers and a sister, Margaret (known as Jean). His older brother, Bill, was a star chemical engineer; his younger brother, Dick, took over his father's advertising business, which he developed into Omaha's second largest agency. His sister Jean majored in science and became a professor of pathology at the University of North Dakota.

Holland was one of the most influential psychologists of the twentieth century, and his impact on vocational psychology continues into the twenty-first century. He is well known for his Theory of Vocational Personality Types, which has become known simply as Holland's theory, as well as for his interest inventory, the Self-Directed Search. Holland's original theoretical article, published in 1959, introduced a model of interest assessment and career interventions. In 1966, he published *The Psychology of Vocational Choice,* which he called "a little book," that described his theory of vocational personality types in detail and provided substantial research evidence to support many of his constructs. In 1958 he published the Vocational Preference Inventory (VPI) but his Self-Directed Search (SDS), published in 1970, supplanted the VPI. The SDS continues to be a popular measure used to assess interests in research and career counseling settings.

One reason for the popularity of Holland's theory is the parsimony of the model which translates easily into career counseling. His theory proposes that vocational interests can be categorized into six types – Realistic, Investigative, Artistic, Social, Enterprising, and Conventional – or some combination of the six types. The Realistic Type includes interests in working outdoors, with things rather than ideas, and with machines. The Investigative Type includes interests in scientific activities, solving problems, and analysis of data and ideas. The Artistic Type values self-expression and creativity especially in music, art, and writing. The Social Type prefers group and humanistic activities, and solving problems by understanding feelings and interpersonal relations. The Enterprising Type prefers organizational activities that include selling and leading and persuading others. The Conventional type has interests in activities that require attention to detail and accuracy as well as numerical activities. The structural arrangement of the six types (R-I-A-S-E-C), hypothesized by Holland, has been shown repeatedly to resemble a six-sided polygon or hexagon. The types adjacent to one another on the polygon (e.g. R-I and E-C) have more in common than do diametrically opposed types (e.g. R-S, I-E, and A-C).

Holland's six types can be used to describe an individual person's interests as well as to summarize the most salient activities in work environments, jobs, and occupations. Furthermore, Holland predicted that people will choose to enter occupations that are congruent with their interests. Holland also proposed that positive outcomes, such as job satisfaction and performance, and job tenure, occur when a person's interests match the requirements of the environment (i.e. have P-E Fit).

To help vocational counselors use his theory with clients, Holland constructed two interest inventories – the VPI and the SDS. The SDS is a more popular choice than the VPI because the inventory can be self-scored. In other words, the client or the test administrator can easily calculate the scores for the scales that assess interest in the six types. Most other interest inventories must be scored by a scoring service, which increases the price of the inventory. Thus, the SDS is a relatively inexpensive option both for use with clients and for use in research that studies questions related to vocational interests. In 2009, Holland's publisher estimated that the SDS, available in 25 languages, had been taken by 29 million people.

Holland developed several other assessment instruments including the Vocational Identity Scale (1993), the Career Attitudes and Strategies Inventory (1994), and the Position Classification Inventory (1998), but the SDS clearly is his most popular inventory. One of Holland's most frequent collaborators was Gary Gottfredson, and together they developed "Holland Codes" for hundreds of occupations. These codes, published in the *Dictionary of Holland Occupational Codes* (Gottfredson, Holland, & Ogawa, 1982), provide a shorthand for describing the most important interests for an occupation. For example, chemical engineers are coded Investigative, Realistic, Enterprising, and art directors are coded Artistic, Enterprising, Social. The codes also provide counselors and clients with valuable occupational information to use in career decision-making. Holland and his colleagues also developed "Holland Codes" for college majors and leisure activities.

Holland grew up in Omaha attending Washington School and graduating from Central High School. He lived on Pine Street where the family home had enough acreage for fruit trees, gardens, and a playground including a football field and miniature golf course. He did his undergraduate work at the Municipal University of Omaha (now University of

Omaha) majoring in psychology, French, and mathematics and graduated in 1942. His brother Bill described him as Dean William Thompson's "fair-haired boy." Thompson was a clinical psychologist and, incidentally, Warren Buffett's father-in-law.

Upon completing his undergraduate degree Holland enlisted in the Army. Even at a young age, his vision was poor and for most of Holland's professional life his vision was borderline for obtaining his driver's license. In 1942, poor vision was not a reason to fail the military physical but his vision, along with his major in psychology, likely did lead to Holland's military assignment to positions such as classification interviewer, test proctor, psychological assistant, and Wechsler Intelligence Test administrator rather than an assignment with the infantry. Holland's daughter, Jean Holland, believes that his work interviewing hundreds of new Army recruits, led him to conclude that people could most likely be classified into a relatively small number of types.

After completing three and a half years in the Army, Holland entered graduate school to study psychology at the University of Minnesota. He completed his MA in 1947 and his PhD in 1952. Holland credits Herbert Feigl's philosophy of science course with stimulating his interest in theory during graduate school, and later a critique of his theory by Bill Alston, a Michigan philosopher, with helping him to hone a defensible theory. Holland's graduate education also provided a heavy dose of "Dustbowl Empiricism" that was driven by psychologists such as Donald G. Paterson, Edmund G. Williamson, and John D. Darley, who approached psychology with a "show me the evidence" philosophy.

Holland's own interests also shed some light on his career path. His Investigative interests (I Type), of course, were evident in his theoretical writings and research that culminated in over 200 publications. His Enterprising interests (E Type) contributed to his efforts to publicize and market his assessment instruments, especially the SDS and his theory. Holland also was an enthusiastic pianist from an early age. He continued to take lessons and practice throughout his lifetime and gravitated toward classical music. His Artistic interests (A Type) also were evident in his substantial graphic, oil, and water color art collection.

Initially, Holland worked in applied psychology settings. He worked at the Western Reserve University counseling center for three years (1950–1953), then at the Veterans Administration Psychiatric Hospital in Perry Point, Maryland (1953–1956), the National Merit Scholarship Corporation for six years, and the American College Testing Program (ACT) for six years. During his time at Western Reserve, he became convinced of the need for more efficient methods for assessing vocational interests as well as for connecting an individual's vocational characteristics to the requirements of the work environment. During his work with National Merit and ACT he had the resources and the opportunity necessary for research and the freedom to develop the VPI and his typological theory. Holland's tenure with ACT, as vice president for research and development, ended over a disagreement with the president about an administrative decision involving the development of an ACT product. Reflecting on his firing, Holland acknowledged that his most important work, developing his theory and the SDS, most likely would not have occurred if he had remained with ACT. In 1969, Holland accepted an offer from the Johns Hopkins University in Baltimore as a professor. He retired at the (especially now) young age of 60 (1980) but continued as emeritus professor and as an active scholar. He died in 2008 at the age of 89.

Holland's body of work influenced both the science and the practice of vocational psychology. Some of the most productive researchers in contemporary psychology built their careers on investigations of Holland's theoretical constructs, the application of his theory to a better understanding of career choice and decision-making and person-environment fit, the study of vocational interests, and the assessment of interests in career counseling as well as for research. His name recognition in psychology surely is the equal of other greats in the field (e.g. B. F. Skinner and P. E. Meehl). From all reports, he was generous with his professional assistance to early career professionals and developed life-long friendships with collaborators as well as with competing interest inventory authors.

Holland's theory has stimulated decades of scholarship and research in vocational psychology, career development, and interest measurement. And his theory also has had a tremendous impact on interventions in career counseling. Holland's theory brought order and focus to the field of vocational interest assessment which had previously been primarily atheoretical in its orientation. This structure and focus helps career counseling clients to better understand the relations among their interest as well as the way in which their vocational types fit into, and are operationalized by, the world of work.

Holland's theory has been employed around the world. His work is so well known in Australia, for example, that a book titled *Holland in Australia* (Lokan & Taylor, 1986) was published. His SDS has been translated in numerous languages other than English. Holland's types also have been integrated into several other interest inventories (e.g. the Strong Interest Inventory and the Campbell Interest and Skill Survey) as well as the Department of Labor's coding of occupations, the O*NET, and the Department of Defense's ASVAB Career Exploration Program. Articles related to his theory and the SDS have been published in over 178 journals worldwide (Reardon, 2009), and Holland is one of the most frequently cited of any psychologist in the past half century.

Holland received numerous recognitions for his intellectual contributions including honorary doctorates from Doane College (Crete, Nebraska), the University of Nebraska, and the University of Minnesota. He was a Fellow of the American Psychological Association (APA) in the specialties of counseling psychology and educational psychology, and president of the Society of Counseling Psychology. His many awards included the E. K. Strong, Jr. Gold Medal for Contributions to Interest Measurement (1974); Eminent Career Award from the National Vocational Guidance Association (now National Career Development Association; 1980); Distinguished Lifetime Contribution to Counseling Psychology (1990); Walter Storey Career Development Professional Award from the American Society of Training and Development (1990); the American Counseling Association's Extended Research Award (1995); and Distinguished Professional Contributions to Knowledge Award (1995) and Distinguished Scientific Application of Psychology Award (2008) from the APA. Holland also was the first recipient of the Society for Vocational Psychology's Distinguished Achievement Award in 2005.

Holland and his wife, Elsie, had three children. He described his daughter Kay as an "ASE...Big A" (Artistic-Social-Enterprising) book binder, ballet dancer, musician, teacher (Weinrach, 1990). His daughter Jean's code is SIA (Social-Investigative-Artistic) and she has worked as a counselor-statistician. His son, Bob, is a Realistic (R) Type and has worked as a driver for various industries and as a carpenter.

Matarazzo, Joseph D.

John C. Linton

West Virginia University School of Medicine

Joseph D. Matarazzo was born in Italy to parents who were US citizens. He completed the first 12 years of his education in the public schools of Schenectady, New York. Following his high school graduation in 1943, he served on active duty in the US Navy for six months before being selected for officer training. Because of the wartime need for young officers, this program accelerated four years of college education into 28 months, which Matarazzo completed through the Navy V-12 Program at Columbia University (eight months) and the Naval Reserve Officers' Training Program at Brown University (20 months). Following his June 1946 graduation from Brown University with a Bachelor of Arts degree in naval sciences and a commission as an ensign, Matarazzo served aboard a navy oil tanker in the Far East.

A year after leaving Brown where he had not taken even one psychology undergraduate course, Matarazzo sent an application from the Pacific to Brown and was accepted as a postbaccalaureate graduate student in the psychology department. At Brown, he spent his first year as a graduate student taking the nine courses required for an undergraduate major in psychology. His classroom and social interactions with Brown's small cadre of graduate students during the 1947–1948 school year remain among Matarazzo's most memorable experiences. Although he did not know it at the time, this year of graduate study would greatly influence his subsequent choice of a career in academic psychology. That year also influenced his personal life inasmuch as one year later (in 1949) he married one of the graduate students he had met in Brown's psychology department (Ruth Wood Gadbois).

Brown was one of the few universities in the country that offered a doctoral degree in psychology but did not offer a clinical psychology program. Therefore, in the fall of 1948 Matarazzo transferred to Northwestern University after Brown's psychology department Chair, Walter Hunter, wrote a letter on Matarazzo's behalf to his longtime friend, William A. Hunt. This transfer proved to be fortunate, as Hunt was then a role model for the psychologist as a scientist-practitioner.

At the end of Matarazzo's second year of graduate study at Northwestern, he left for an internship with Robert I. Watson and Ivan N. Mensh at Washington University School of

Medicine in St. Louis, Missouri. Just before he completed his one-year internship, the dean of the medical school asked him to stay on for his fourth year of doctoral study to teach a required course in medical psychology to first-year medical students. The dean got permission from Northwestern for Matarazzo to take the 32 hours of courses for his doctor of philosophy minor at Washington University School of Medicine and to have those credits transferred to Northwestern.

Matarazzo taught at Washington University School of Medicine (1952–1955) and then at the Harvard Medical School (1955–1957). After these appointments, he established the first administratively autonomous department of medical psychology in the United States, at the Oregon Health Sciences University, and he served as the department's chairman from 1957 until he resigned the position in 1996. In 1996 he became a tenured professor of behavioral neurosciences.

Matarazzo's 44 years on the faculty of the Oregon Health Sciences University Medical School provided a fertile environment for him to contribute to furthering the application of psychology in three ways. First, he contributed to the advancement of psychological assessments. In 1972 he wrote the fifth edition of *Wechsler's Measurement and Appraisal of Adult Intelligence*, which served as a required textbook for a generation of graduate students in clinical, counseling, school, and industrial-organizational psychology.

Second, his four-decade tenure as a member of the board of directors of his university hospital's medical staff provided full staff voting membership for the other members of his clinical psychology faculty and, along with his forceful publications on this subject, helped pave the way for psychologists to be admitted to full voting membership at other university and community hospitals. Using his medical school base, Matarazzo demonstrated the ability of psychologists to serve as consultants to their physician colleagues in departments of medicine, pediatrics, obstetrics-gynecology, and neurology, rather than exclusively to associates in departments of psychiatry. He thus served as a role model in helping psychologists throughout the country expand their work with nonpsychiatrist physicians.

Third, during the 1970s Matarazzo further extended the scope and promise of the potential partnership of psychology and medicine as one of the principal founders of the American Psychological Association (APA) Division of Health Psychology, while he concurrently helped to establish behavioral health and behavioral medicine as a viable clinical and scientific bio-behavioral partnerships for both professions. From that base, he also served during the next two decades as a catalyst for the establishment of the European Society of Health Psychology, the Italian Society of Health Psychology, the Japanese Association of Health Psychology, and the Asian Association of Health Psychology.

Matarazzo promoted the development and growth of psychology in other countries of the world in a number of leadership positions at the international level. These included serving as president of the International Council of Psychologists (1976–1977), a member of the executive committee of the board of directors of the International Association of Applied Psychology (1986–2002), United States Delegate from the US National Academy of Sciences to the International Union of Psychological Sciences to the International Union of Psychological Science (1994–1998), and as president of the International Congress of Applied Psychology (1998).

Over the years, Matarazzo has served as president of such organizations as the Academy of Behavioral Medicine Research, the International Council of Psychologists,

the Western Psychological Association, the APA Division of Health Psychology, the American Association of State Psychology Boards, the American Psychological Foundation, and the American Psychological Association (1989–1990). He was also one of the founders of the Council of Graduate Departments of Psychology and served on its charter executive committee.

He has served on National Institutes of Health (NIH), National Institute of Mental Health (NIMH), and National Science Foundation training committees, advisory panels and study sections, and he has served as the charter chairperson of the NIH Behavioral Medicine Study Section. He served for 20 years as the psychology editor for *Stedman's Medical Dictionary*, and has served over the years on the editorial boards of nine APA journals, and served on the editorial boards of 16 other scientific and professional journals. In 1991 he was appointed by the US Secretary of Health and Human Services to a four-year term on the NIMH Mental Health Advisory Council.

Matarazzo's awards include the annual Award for Contributions to Health Psychology from APA's Division of Health Psychology, the annual Distinguished Scientist Award from APA's Division of Clinical Psychology, the annual Distinguished Service to the Profession of Psychology Award from the American Board of Professional Psychology, the annual Research Award (Hofheimer Prize) of the American Psychiatric Association, and the 1991 Award for Distinguished Professional Contribution to Knowledge from the American Psychological Association.

His academic interests included behavioral cardiology, then a nascent area of study that is a now critical focus in the cardiology community. For years he served as a familiar beacon for how clinical psychologists could contribute to schools of medicine, the training of medical students and residents, and patient care.

He developed training programs for psychology students and interns that were novel, clearly ahead of their time, and became a model that slowly gained the attention of psychology graduate programs across the country. His hundreds of publications and presentations underscored how patients in medical settings, and medical and allied health students in training could benefit from the knowledge and skills provided by clinical health psychologists.

During his tenure as president of the American Psychological Association in 1989, Dr. Matarazzo continued to champion the value of psychologists in the health care system. He was also instrumental in the formation of the Association of Psychologists in Academic Health Centers, a now robust organization of 4,000 that represents the interests of psychologists teaching and serving in health science centers in the United States and Canada.

Many psychology graduate students now enter universities choosing a career track to provide services to medical patients with or without mental health challenges, the path he walked alone for many years, and a path now well worn by thousands who have followed him. Innumerable students, patients, and medical practitioners have benefited from his vision and perseverance.

Dr. Matarazzo's contributions have led to thousands of articles, books, presentations, and discussions in the general press and social media regarding psychological factors in health and illness. His important contributions include research and scholarly work, including influential offerings on measurement of intelligence (Lindemann & Matarazzo, 1990), the clinical interview (Matarazzo, Saslow, Matarazzo, & Phillips, 1958), and assessment.

He also authored an exceptional series of articles on behavioral pathogens and behaviors that impair our health (Matarazzo, 1984) and worked to reshape psychology's role and image in medicine, modern medical centers, and schools of medicine (Matarazzo, Lubin, & Nathan, 1978).

His success in building the nation's first psychology department in a medical school and transforming the role of psychology in medicine, and his critical role in the development of other free-standing psychology departments in medical schools, including the Department of Medical and Clinical Psychology at the Uniformed Services University of the Health Sciences, stand among his most enduring contributions to the field and to the betterment of the human condition. He ignited and led a revolution in health psychology and behavioral medicine that has reshaped medical science and practice.

McClelland, David C.

Richard E. Boyatzis

Case Western Reserve University

David C. McClelland, formerly of Harvard University and Boston University
  Areas of research: human motivation, operant measures, competencies, health, leadership

Early Life and Educational Background

Born: May 20, 1917, in Mt. Vernon, New York, USA
  Died: March 27, 1998, in Lexington, Massachusetts, USA
  Married first: Mary Sharpless, 1938, five children: Catherine, Duncan, Nicholas, Sarah, Jabez; second Marian Adams, 1984, two children: Mira and Usha
  Completed PhD in psychology, Yale University, 1941
  Professor at Wesleyan University, Connecticut 1942–1956; American Friends Service Committee and Instructor, Bryn Mawr College, Pennsylvania, 1943–1945
  Programme Director, Ford Foundation, 1952–1953
  Harvard University, 1949–1950, 1956–1987, professor and chairman; Department of Social Relations from 1962–1967, professor emeritus, 1987–1998
  Founded McBer and Company, 1963
  Boston University, professor, 1987–1998

Research Interests

David C. McClelland made major research contributions in motivation, conscious thought, competencies, and healing. He also made major contributions to research in methods by championing conscious thought and thematic coding of the Thematic Apperception Test (TAT) as well as other forms of audio, video, and written documents. As a research psychologist, his work was relatively unique in initiating major programs and fields of endeavor in a wide range of fields from education to clinical practice, management to

economic development, substance abuse treatment to healing sciences. It could be said that there were three major themes in his work directly related to personality and individual differences. The development of the expectancy-value theory of human motives focused on the needs for achievement, affiliation, and power. The second theme was the development of tests and operant methods, such as the TAT, Behavioral Event Interview, and the Test of Thematic Analysis, that have been used in research and applications. The third theme was the development of job-competency studies and methods as a way to link human ability to performance.

A Theory of Human Motives

According to David McClelland, human motivation is "a recurrent concern for a goal state or condition as measured in fantasy which drives, directs and selects the behavior of the individual." Working with Henry Murray in the 1940s, he focused on three particular motives: the Need for Achievement (N Ach); the Need for Affiliation (N Aff); and the Need for Power (N Pow). His work focused from the late 1940s through the 1960s was focused on N Ach. In the late 1960s and through to the 1990s, N Pow emerged as the focal point of his research.

The Need for Achievement is an unconscious drive to do better toward a standard of excellence. People with strong Need for Achievement measure themselves against specific goals. They prefer moderate risks, prefer individualistic activities, recreation involving getting a score, like bowling, and prefer occupations with individual performance data, like sales.

The Need for Power is an unconscious drive to have impact on others. People with strong N Pow often assert themselves by taking leadership positions, gambling, drinking alcoholic beverages, and committing aggressive acts. They often have high blood pressure, and prefer interpersonally competitive sports, such as football. They like to collect possessions that connote prestige to others and prefer occupations in which they can help or have impact on others, like teachers or leaders.

The Need for Affiliation is an unconscious drive to be a part of warm, close relationships, like friendships. People with strong N Aff choose to spend time with close friends or significant others, like to write letters or telephone friends or family, prefer to work in groups and are sensitive to others' reactions. They prefer collaborative activities and occupations in which they work closely with others, such as elementary school teachers and counselors.

Beyond the separate motives, McClelland emphasized the pattern of one's relative motive strength. His claimed that everyone has some level of the motives, but the relative dominance varied. The pattern of a person's motive strength is indicative of occupational performance. For example, high N Ach, low N Aff, and moderate N Pow is characteristic of successful entrepreneurs throughout the world. High N Pow, moderate to low N Aff, moderate N Ach, and high Activity Inhibition (i.e. a measure of self-control) is characteristic of effective leaders, middle-level and executive managers.

In addition to studying motives of individuals, David McClelland initiated a series of studies of motivational trends of societies. He established an empirical link between motivational

themes in cultural modes of expression (e.g. hymns, myths, and children's books) and national events (e.g. the rise and fall of an economy, social movements, and wars).

McClelland's definitions, data, and applications were cited as the most useful approach to motivation in a study by the former accounting firm Touche Ross & Company in 1981.

In Search of Operant Tests and Measures

David McClelland had been a proponent of operant methods (i.e. tests where a person must generate thoughts or actions) from his early days of research in the US Navy on submariners in the 1940s. He argued that operant methods had greater validity and sensitivity than respondent measures (i.e. tests calling for a true/false, rating or ranking response) but were often overlooked by research psychologists because they suffered from less traditional measures of reliability.

In the TAT, a person creates and tells a story about what is happening after looking at a picture for about a minute. As a classic projective test, it moved from the clinician's realm into research with Henry Murray's work in the 1920s. The pictures were selected to be somewhat ambiguous and allow the person to project. Later, in the 1970s, McClelland advocated for a direct behavioral sampling of a person's actions, as well as thoughts and feelings through the Behavioral Event interview where a person is asked to, "tell about a time, recently, when you felt effective in your job." This was a modified critical incident interview as described by Flanagan in 1954. But McClelland's insight was to use it to assess a person's behavioral patterns, not just a job or task or situation.

Specifically, McClelland developed compelling evidence to show that operant methods, as compared to respondent methods, consistently show: (1) more criterion validity; (2) less test-retest reliability; (3) greater sensitivity (i.e. discriminate mood changes, style differences, and other somewhat subtle, dynamic aspects of human thought and behavior); (4) more uniqueness and are less likely to suffer from multicollinearity; (5) greater cross-cultural validity because it did not require a person to respond to prepared items; and (6) increased utility in applications to human or organizational development.

The key to rigorous research and ethical use of operant methods is the process of reliably coding the raw information, whether from audio, videotapes, or historical documents. McClelland extended thematic analysis from a highly unreliable, clinical art form to a legitimate research method. To achieve validity, the coding of the raw information requires consistency of judgment, or inter-rater reliability. It is difficult, if not impossible, to achieve reliability without a clear, explicit codebook. The use of codebooks and reliable coding opened the doors to many new measures. These measures, in turn, allowed creative inquiry into a wide range of people's behavior and outcomes.

Job Competencies and Assessing Behavior

McClelland and colleagues in 1958 conceptualized a broad array of skills as a reflection of a person's capability. Reviving his earlier personality theory from 1951, McClelland and his

colleagues at McBer and Company expanded the search for competencies in the early 1970s (i.e. skills, self-image, traits, and motives) with operant methods in many occupations. In this approach, the definition of a job competency differs from many behaviorist approaches to the identification of skills in that the job-competency definition requires that the person's intent be understood, not merely observation of the person's actions. As a result of this inductive design and using operant methods, there was an emphasis on characteristics of the "person," rather than the tasks involved in a job.

Using operant methods to explore the differences in thoughts, feelings, and behavior of superior performers as compared to average or poor performers, competency models were developed and validated against performance in a job. Studies were completed on bank tellers, social workers, police, priests, generals and admirals, executives, sales representatives, scientists, programmers, project managers, and so forth.

The competency assessment methods developed a picture of how the superior performer thinks, feels, and acts in his work setting. This contextual and concrete picture provided case studies and models for how to help anyone in a job, or aspiring to one, develop their capability. As professionals in organizations were trained in the techniques of job-competency assessment, they developed competency-based training programs, career path systems, developmental assessment programs, coaching and guidance programs, recruiting, selection, and promotion systems. Because of its face validity and growing use by practitioners, academic researchers were alarmed. It took another 30 years before scholarly research was appearing regularly in peer reviewed journals.

In his last published work, David McClelland extended understanding of the impact of competencies on performance by postulating a "tipping point." In addition to knowing which competencies are needed to be effective in a job, he examined a way to determine how much of each competency was sufficient to attain outstanding performance.

Helping People Change

One of David McClelland's somewhat unique perspectives was a refined sensitivity to relevance of one's research. He wanted to develop insight that might help people and our social systems be more humane as well as effective and innovative. It began with McClelland's concept of changing motives – if you know how people with a certain motive think and act, a person changes their motives by changing the ways they think and act. After years of experiments in countries throughout the world, several observations can be made: people can change the shape of their motive profile; people will only change if they want to change; change cannot occur without a change in the person's environmental supports; and any of these attempts at motivational change increased a person's sense of efficacy.

The earliest efforts by McClelland were to stimulate business and economic development by training small business owners in achievement thinking and behavior. It worked in India and other countries and then with minority owned and operated small businesses in the United States. The method was extended to the power motive in efforts to help alcoholics and then executives and middle-level managers in industry, even within the context of community development.

Concluding Thoughts

David C. McClelland had an impact on many fields and scholarly traditions. Through his own work and over the decades and that of his former doctoral students, and now their doctoral students, he has directly and indirectly trained legions of scholars, consultants, and leaders – stimulating their curiosity, guiding and often provoking them to contribute to various occupational fields and professions. He was a founder or influential director of over 14 for-profit and not-for-profit research and consulting companies, the most notable of which is McBer and Company, now The Hay Group/Korn Ferry. Most of all David was, to many of us, a close personal friend, as well as a colleague.

Beck, Aaron T.

Lena C. Quilty

University of Toronto

Dr. Aaron T. Beck has profoundly shaped clinical research and practice, providing the theoretical framework and standardized tools and protocols crucial to current evidence-based psychological assessment and treatment. Dr. Beck was a seminal figure in the development of cognitive theories of psychopathology and is widely regarded as the father of cognitive therapy. He notably authored a series of assessment instruments that remain some of the most widely used measures of affective symptomatology in both research and practice today. Dr. Beck founded and remains the President Emeritus of the Beck Institute for Cognitive Therapy and Research. He is further professor emeritus at the University of Pennsylvania, where he founded the Psychopathology Research Unit. Dr. Beck is the Honorary President of the Academy of Cognitive Therapy, and has received numerous awards, honors, and honorary degrees in recognition of his contributions to the field. He has published over 600 scholarly articles and 25 books; he was designated one of the five most influential psychologists of all time by *The American Psychologist*, and continues to be actively involved in theoretical and applied research.

Dr. Beck was born in 1921 in Providence, Rhode Island. He received his undergraduate degree magna cum laude from Brown University in 1942, and his medical degree from Yale University in 1946. He completed residencies in pathology and neurology, and subsequently acted as a fellow for two years, accruing experience in psychiatry and psychotherapy. Dr. Beck joined the University of Pennsylvania Department of Psychiatry in 1954, where his early research failed to demonstrate support for the psychoanalytic model of depression. Rather, Dr. Beck observed that depression was associated with reflexive thoughts such as self-criticism and pessimism. He captured depressive symptoms and associated cognitions in the *Beck Depression Inventory* first published in 1961 (BDI; Beck, Ward, Mendelson, Mock, & Erbaugh, 1961) and then revised in 1996 (BDI-II; Beck, Steer, & Brown, 1996). The BDI-II is among the most widely used patient-report measures of depressive severity in research and practice. The Beck Family of Assessments now further comprises the *Beck Hopelessness Scale* (Beck & Steer, 1988), *Beck Scale for Suicidal Ideation* (Beck & Steer, 1991), and *Beck Anxiety Inventory* (Beck & Steer, 1990) – psychometrically

robust and clinically useful multiple-choice symptom scales assessing the moods, cognitions, and other clinical features relevant to these domains of illness.

Dr. Beck characterized the "negative cognitive triad" (i.e. the negative beliefs about the self, the world, and the future) and the "cognitive distortions" (i.e. logical errors, such as catastrophizing, overgeneralizing) evident in depression. He proposed that depressive disorder is in essence a thinking disorder, and that changes in maladaptive thinking styles are both necessary and sufficient to achieve reductions in depressed mood. In a series of landmark clinical trials, he demonstrated that the identification, analysis, and reformulation of depressogenic thought patterns resulted in therapeutic benefit. Through this work, Dr. Beck derived a protocolized approach to treatment called cognitive behavioral therapy (CBT) wherein patients identify, analyze, and restructure the maladaptive thinking styles contributing to the maintenance of their distress. This treatment approach has been described as "collaborative empiricism" to reflect the partnership between the therapist and patient in the evaluation of thinking patterns and resolution of symptoms. CBT is typically characterized as goal-oriented, present-focused, time-limited, and structured. Treatment includes concrete goals, psychoeducation, and activities and skills-building in identifying thoughts associated with current negative moods, evaluating evidence and utility of those thoughts, and developing alternate thoughts not similarly associated with distress and problematic behavioral patterns. Thoughts include interpretations of specific situations or *automatic thoughts* (e.g. "Everyone thought my presentation was terrible"), as well as the polarized *dysfunctional attitudes* (e.g. "If I do not do something perfectly, I have failed completely") and *core beliefs* (e.g. "I am incompetent") that underlie them. Exercises to facilitate cognitive restructuring at each of these levels of thought span imaginal and behavioral exercises, thought records and utility analyses, and are conducted with a form of questioning described as "Socratic dialogue" to facilitate patient self-exploration.

Dr. Beck co-authored several early volumes outlining the theoretical foundation and procedures of CBT in detail, which gained widespread attention and acceptance during the "cognitive revolution" in the 1970s. He published *Cognitive Therapy of Depression* with Rush, Shaw, and Emery in 1979; this volume forms the basis for the most widely used CBT protocols of depression today.

Cognitive models and CBT treatment protocols have been successfully extended to the treatment of anxiety disorders (Beck, Emery, & Greenberg, 2005), substance use disorders (Beck, Wright, Newman, & Liese, 1993), personality disorders (Beck, Freeman, & Davis, 2003), psychotic disorders (Rector & Beck, 2002), and more. Dr. Beck thus has had a critical role in the conceptualization and treatment of a wide range of psychological difficulties. His innovation is matched only by his leadership, evident in his role in professional organizations such as the Academy for Cognitive Therapy and professional meetings such as the World Congress of Cognitive Therapy. Indeed, Dr. Beck has balanced his empirical attention to clinical theory, assessment, and treatment with ongoing promotion of and advocacy for training, mentorship, networking, and collaboration throughout his career.

Although empirical work for the cognitive models and treatment abounds for a wide range of psychiatric disorders, the application of cognitive theory to depression provides a useful illustration of evolving research in this area. After his foundational research, Dr. Beck expanded his cognitive theory of depression to incorporate continued, emerging research, including that relevant to the information processing biases and neurobiological

underpinnings or biomarkers of depression. More specifically, Drs. Clark and Beck (2010) proposed that environmental stressors interact with genetic and personality vulnerabilities, resulting in the activation of negative cognitive "schemas." The activation of maladaptive schemas results in automatic and biased information processing such as biases in attention, memory, and executive function. These biased cognitive processes are in turn linked to specific neurological substrates such as reactivity in the amygdala and hippocampus. Cognitive therapy corrects biased cognitive processing by either reducing automatic, biased processing and/or by strengthening more effortful or reflective processing, which is linked to neurological substrates such as the anterior cingulate, medial and lateral prefrontal, and orbitofrontal cortex. In short, Clark and Beck (2010) propose that the therapeutic benefit of cognitive therapy is mediated by cognitive changes with specified neurobiological substrates.

CBT is commonly regarded as the best-established psychological treatment for depression. It arguably boasts the largest evidence base, accounting for the majority of studies included in meta-analyses of psychotherapy for depression. Evidence robustly supports the efficacy of CBT in the treatment of depression, equivalent to that of other psychotherapies as well as pharmacotherapy (see Beck & Dozois, 2011). Moreover, CBT is associated with decreased relapse rates, suggesting that it targets ingredients crucial for sustained health.

Seminal reviews have synthesized the evidence for the cognitive mediational model in depression, namely that change in cognition is the causal mechanism of action within this treatment modality (e.g. Garratt, Ingram, Rand, & Sawalani, 2007). These reviews clearly support the presence of negative thoughts in those with depression, the improvement in negative thoughts over treatment with CBT, and the association between improvement in negative thoughts and in depression over treatment with CBT. Further, marked improvements or "sudden gains" during the course of CBT have been preceded by changes in negative cognition, further suggesting that these cognitive changes were responsible for that symptom reduction.

Yet, negative thoughts are not specific to depression, and appear to change in response to other psychotherapies and to pharmacotherapy for depression as well. Further, research suggests that change in cognition does not fully account for change in symptoms over treatment, and further, that symptom change can occur in the absence of cognitive change. Sudden gains have also been demonstrated outside of the treatment and even during inactive control treatments. These results suggest that maladaptive thinking patterns are a consequence or associated feature of depression, which resolves with the illness, and may not be causally linked to treatment. In a seminal review, Whisman (1993) submitted that the cognitive mediational model entails that cognitive change is associated with depression change, and that cognitive change is specific to CBT. Later, Garratt and colleagues (2007) suggested instead that as cognitive change is likely directly or indirectly targeted during most psychosocial treatments, the optimal test of cognitive specificity is a contrast between CBT and pharmacotherapy – wherein cognitive change may occur within the latter, but is not of causal significance. Although some research has suggested that changes in cognitive structure are indeed found in CBT but not pharmacotherapy (Dozois, Bieling, Patelis-Siotis, Hoar, Chudzik, McCabe, & Westra, 2009), other research has been unable to demonstrate this specificity (Quilty, Dozois, Lobo, Ravindran, & Bagby, 2014).

Thus, although reviews have documented considerable evidence consistent with cognitive mediation of outcomes, few investigations have been conducted in accordance with these recommendations and conducted formal investigation of cognitive mediation or specificity. Studies frequently include limited assessment of cognition, comparator conditions, sample sizes and follow up periods; together, these design features preclude the ability to support a causal association between change in cognition and change in depression severity over treatment. Thus, although CBT is among the best-established treatments for depression and yields lasting therapeutic benefits, the underlying mechanisms of its impact upon symptoms have yet to be confirmed (see Lemmens, Müller, Arntz, & Huibers, 2016 for a more recent review).

Seligman, Martin E. P.

Arthur J. Schwartz

Widener University

Learned Helplessness

Seligman was born in Albany, New York, in 1942 and earned his bachelor's degree in philosophy at Princeton University in 1964, graduating Summa Cum Laude. Seligman received his PhD in psychology at the University of Pennsylvania in 1967 and it was during this period, as an extension of his research on depression, that he began to conceptualize and develop his theory of "learned helplessness."

While conducting experimental research on classical conditioning for his PhD, Seligman inadvertently discovered that dogs that had received unavoidable electric shocks failed to take action in subsequent situations – even those situations in which escape or avoidance was in fact possible. Eventually, Seligman coined the term "learned helplessness" to describe the mental state that individuals experience when they have endured repeated painful or aversive stimuli that they are unable to avoid. Since his discovery, learned helplessness has become a basic principle of behavioral theory that explains why individuals may accept and remain passive in negative situations despite their clear ability to change the circumstance. In his book *Helplessness* (1975), Seligman argues that these negative expectations contribute to low self-esteem and chronic failure. His research on learned helplessness was supported by the National Institute of Mental Health, National Science Foundation, and the MacArthur Foundation, and the theory has been applied to many conditions and behaviors including clinical depression, aging, domestic violence, academic failure, poor health, drug abuse, and alcoholism. More recently, Seligman has reformulated his theory of learned helplessness to include attributional style.

Learned Optimism

In his public talks, Seligman frequently shares with audiences a story that illustrates his shift away from understanding learned helplessness to examining the principles of learned

optimism. Seligman loves to garden. As he explains, one day he is in his garden with one of his daughters, Nicki, who is about to turn six. Nicki is having fun, spraying dirt and throwing weeds everywhere. Seligman describes yelling at his daughter to stop. Nicki proceeds to walk over to her father with a stern look on her face. "Daddy," she tells her father, "from the time I was three until I was five, I whined a lot. But I decided the day I turned five, to stop whining. And I haven't whined once since I turned five." At this moment, according to Seligman, his almost six-year-old daughter looks him right in the eye and says: "And daddy, if I can stop whining, you can stop being such a grouch" (Seligman, 2002).

Seligman's book *Learned Optimism*, published in 1990, examines the differences between pessimists and optimists in terms of their different explanatory styles. Seligman argues that anyone can become an optimist by using various "self-talk" methods and techniques. The one essential step, Seligman asserts, is developing the ability to *dispute* the reasons or beliefs individuals typically give when facing an adverse situation or setback. In 1990, Seligman established The Penn Resiliency Program, in collaboration with his co-investigators Jane Gillham and Karen Reivich, to conduct a series of longitudinal, controlled studies to determine the effectiveness of these methods and techniques. The studies consisted of a school-based cognitive-behavioral intervention to prevent depression and anxiety among middle school students. These studies, funded by the National Institute of Mental Health and the US Department of Education, indicate that the techniques introduced in *Learned Optimism* can prevent and reduce symptoms of depression and anxiety, although some inconsistent findings were reported. Significantly, the studies reveal that the positive effects appear to be long-lasting. Seligman and his colleagues describe their theoretical approach and interventions in the book *The Optimistic Child* (1995). During this period of time Dr. Seligman also directed the Clinical Training Program within the Department of Psychology at Penn.

Positive Psychology

Seligman is widely considered one of the pioneers of positive psychology. For example, in 1998, as president of the American Psychological Association, he selected positive psychology as his presidential theme. However, it should be noted that from its inception Seligman closely collaborated with a number of distinguished psychologists to develop and explore the concepts, theories, and empirical evidence underpinning the study of positive psychology. Mihaly Czikszentmihalyi, Donald Clifton, George Valliant, Christopher Peterson, Daniel Kahneman, and Ed Diener are among the many psychologists who helped launch what is known today as the field of positive psychology.

In general, positive psychology is the study of the conditions and processes that contribute to the flourishing or optimal functioning of people, groups, and institutions. More recently, positive psychology has focused on the scientific study of human strengths and virtues. The 2004 handbook *Character Strengths and Virtues*, co-written by Seligman and Christopher Peterson, established the theoretical and empirical roadmap by which psychologists could connect their own lines of research to the emerging field of positive psychology. The handbook, what Seligman and Peterson often referred to as the "un-DSM,"

identified six classes of virtues and 24 character strengths. The six virtues are wisdom, courage, love and humanity, justice, temperance, and transcendence. The 24 character strengths include curiosity, creativity, persistence, integrity, kindness, fairness, leadership, forgiveness, humility, gratitude, and hope, among others. One chapter of the handbook is devoted to each of the 24 character strengths. The research for the handbook was supported by the Values in Action Institute, a nonprofit initiative of the Manuel D. and Rhoda Mayerson Foundation, directed by Dr. Neal Mayerson.

From the beginning, Seligman and his colleagues made every effort to involve young and mid-career scientists in developing the field of positive psychology. Seligman introduced the American Psychological Association (APA) to the John Templeton Foundation, and in 2000 the Foundation awarded the APA a substantial grant to establish the Templeton Positive Psychology Awards. During the next three years, these awards were given annually to young or mid-career researchers. A decade later, many of these researchers remain at the forefront of positive psychology, taking on positions of leadership within the discipline as well as continuing to conduct and disseminate research that informs and expands humanity's understanding of what Seligman calls "the best things in life." Recipients of the Templeton Awards include Barbara Frederickson, Sonja Lyubomirsky, Lisa Aspinwall, Laura King, David Lubinski, Kennon Sheldon, Laura Kubzansky, Suzanne Segerstrom, Jonathan Haidt, Dacher Keltner, and Michael McCullough.

The first book Seligman wrote about positive psychology for the general audience was *Authentic Happiness* (2002). The first sections examine the three pillars underpinning the study of positive psychology: positive emotions, positive traits (strengths and virtues), and positive institutions. In the final section, Seligman offer a response to the Aristotelian question "What is the good life?" He identifies three pathways: the pleasant life, the good life, and the meaningful life. The pleasant life is focused heavily on the hedonic, the pursuit of physical pleasures that excite our senses and positive emotions. The good life consists of finding balance between the different areas of life (work, play, love) and leveraging our signature strengths to experience as much flow as we can. The meaningful life occurs when we experience a deep sense of fulfillment because our life is connected to noble purposes beyond our own cares and concerns.

Seligman established the Positive Psychology Center at the University of Pennsylvania in 2001. The Center is home to many scholarly, research, and field-building initiatives. In 2005, Seligman established, in collaboration with his colleague James Pawelski, a master's program in Applied Positive Psychology, and since the MAPP's inception hundreds of professionals in different domains and across the globe (including business and nonprofit leaders) have examined the principles of positive psychology within the context of their own profession and areas of expertise.

Dr. Angela Duckworth, one of Seligman's former graduate students, established her research lab at the Center to study the relationship between grit, self-control, and achievement. Seligman and colleagues are also examining which "health assets" produce stronger health, an initiative supported by the Robert Wood Johnson Foundation. The Center is home as well to the World Well-Being Project, a collaborative effort between computer scientists, psychologists, and statisticians to shed new light on the psychosocial processes that affect health and happiness.

In 2011, Seligman wrote *Flourish: A Visionary New Understanding of Happiness and Well-being*. In the first chapter he offers a strong critique of happiness as the current gold standard of positive psychology, arguing that happiness is too dependent on mood. In its place, Seligman elevates well-being as the new gold standard. Asserting that well-being has five elements, he developed the mnemonic PERMA to explain each component. The first element of well-being is positive emotion (fully explained in his earlier book *Authentic Happiness*). The second is positive engagement, how often we are absorbed in an activity that allows us to enter into the state of flow. Positive relationships is the third element, the extent to which we have significant friends, family, and neighbors. Chris Peterson, one of the founders of positive psychology, underscored the importance of this element whenever he was asked to explain what positive psychology was about in a just a few words. He always replied "Other people." The fourth element is positive meaning, the pursuit of noble purposes that extend beyond our own needs and concerns. The final element of well-being is positive accomplishment, the notion that we are creatures who actively pursue success, achievement, and mastery.

Seligman highlights his work with the US Army in Chapter 7 of *Flourish*. The Positive Psychology Center received funding from the Army to help implement the Army's Comprehensive Soldier and Family Fitness program, an initiative aimed at increasing resilience and reducing post-traumatic stress. The cornerstone component of the program is a train-the-trainer module whereby sergeants in the Army come to Penn for eight days to receive Master Resilience Training. Months later these sergeants then roll out the same program to their soldiers. Seligman participates in these master trainings pro-bono. When the Army conducted an evaluation of the effectiveness of Master Resilience Training in 2013, the results revealed that exposure to resilience training increased various aspects of soldier resilience and psychological health. The evaluation also provided evidence that "soldiers exposed to the training were diagnosed with substance abuse problems at a significantly lower rate than soldiers who were not exposed to the training" (Harms et al., 2013).

Prospective Psychology

In 2012, Seligman and the Positive Psychology Center received two major grants from the Templeton Foundation to further the science of prospection, which is the mental representation and evaluation of possible futures. In 2013, the Center awarded 18 research projects to investigators who seek to measure the mechanisms and applications of prospection, including mapping the neurocognitive mechanisms of prospective thought, the role of dopamine in prospection, animals and prospection, prospection in childhood, and the relationship between prospection and altruism.

Conclusion

Martin E. P. Seligman lives with his wife Mandy and, as he frequently mentions in his talks and books, they have home-schooled five children. He is an avid bridge player who has won over 50 regional championships. Seligman has received two Distinguished Scientific

Contribution awards from the APA and two major awards from the American Psychological Society for his contributions to basic science and the application of psychological knowledge. *A Review of General Psychology* survey, published in 2002, ranked Seligman as the thirty-first most cited psychologist of the twentieth century. Undoubtedly, his ranking for the first decade of the twenty-first century would be considerably higher. He publicly acknowledges that his research interests have long been inspired by Aaron Beck, the renowned psychiatrist at the University of Pennsylvania and the father of cognitive therapy.

The Seligmans live in a home once owned by Eugene Ormandy, a conductor and violinist who became internationally famous as the music director and conductor of the Philadelphia Orchestra. In many ways, Martin Seligman reflects the best qualities and strengths of an orchestra conductor. While early in his career he sought to become a world-class experimental psychologist, his contributions for the past 30+ years have extended beyond basic science. He has embraced his own signature strengths to create networks of psychologists (and funders) who seek to go beyond the profession's historic mission to relieve misery and uproot disabling conditions. In his book *Flourish*, Seligman offers his colleagues a prospective "moon shot" that continues to fuel his own passion and imagination: "I believe it is within our capacity that by the year 2051 fifty-one percent of the human population will be flourishing. That is my charge."

Spielberger, Charles

Thomas Michael Brunner

Dr. Brunner and Associates, Tucson, AZ

Charles Donald Spielberger (1927–2013) – Driven Visionary, Landmark Scholar, Global Diplomat

Charles Spielberger – "Charlie" to those who knew him – was of Hungarian descent. His grandparents, Jack and Julia, emigrated from Hungary to Arkansas in the nineteenth century. Charles' father (A.R.) and his wife (Ellie) moved with Charles and his sister, Joyce from Arkansas to Atlanta, Georgia, when they were young. At first, Charles envisioned joining the family's soft drink business and studied chemistry at the Georgia Institute of Technology (Georgia Tech). After his freshman year in 1945, he changed course and enlisted in the Navy. Completing active duty as a radio and electronics technician (1945–1946), he went on to loyally serve with the Naval Reserves, finally retiring nearly 30 years later – in 1979 – at the rank of Commander. Over many years he provided consultation to areas including the Veterans Administration and the Department of Defense Advanced Research Projects (DARP).

Shortly after his active military service, Spielberger turned toward psychology and never looking away, went on to become one of the most prolific psychologists of the twenty-first century. He chose to undergo his undergraduate and graduate psychological training at the highly revered University of Iowa psychology program. He succinctly completed the following degrees: BA (1951), MA (1953), and PhD (1954). As a graduate student he was mentored by Grant Dahlstrom, PhD, greatly influenced by Hullian and Learning Theory, and inspired by the exceptional teaching of Kenneth Spence, PhD. Spielberger's internship at Worchester State Hospital in Massachusetts, while working alongside psychiatrists associated with the Boston Psychoanalytic Institute, would leave an indelible mark upon him. Charlie's world renowned self-report measures would go on to appreciate the psychodynamically discussed tensions and relationships among powerful upsurges of feeling states and relatively stable personality traits. Charlie's ability to measure the dynamic interplay between "state-like" emotional episodes and patterned frequencies (i.e. "trait-like" aspects)

of the experience, expression, and control of emotions, would be a key reason he went on to become one of the world's foremost experts on the assessment of emotion and personality, and their diverse and powerful effects on physiological health.

Spielberger began his academic career at Duke University with a joint appointment in Psychology and Psychiatry. As a driven researcher, he secured funding from the National Institute of Mental Health (NIMH) to support his experimental research on verbal conditioning. A very long lineage of grant awards would follow from international and governmental organizations. His early career funding to study preventive interventions to alleviate the adverse effects of anxiety on academic performance would light an intellectual fire leading to his exhaustively illuminating the effects of anxiety on test performance leading to major contributions such as the development of the Test Anxiety Inventory (TAI). Developing theory and measures of anxiety – in all of its forms – would remain a lifelong passion carrying Charlie around the world.

Spielberger never was happy to simply publish papers, regarding anxiety or any phenomena that attracted his obsessive brilliance and work ethic; he always sought to connect with the most advanced thinkers in any country to ensure he was on the cutting edge. For example, he facilitated worldwide collaboration on the study of anxiety, as he and Irwin Sarason, PhD, collaborated to obtain a NATO grant with Hans Eysenck to organize a conference on "stress and anxiety in modern life" in Germany. Over the next 45 years, Spielberger would end up being the chairman – or a major facilitator – for many national and international conferences addressing areas including anxiety, anger, personality, stress, and health psychology. Not surprisingly, Spielberger's first book, *Anxiety and Behavior*, was based on a national conference he convened.

After his time at Duke, he transitioned to Vanderbilt University as professor of psychology in 1962. With a seemingly endless amount of energy, during an academic hiatus from Vanderbilt, he conducted site visits and evaluated psychology training programs at more than 100 academic institutions. His acumen as an evaluator of programs prepared him well to become professor and director of Clinical Training at Florida State University, where he completed his work on the development and validation of the State Trait Anxiety Inventory (STAI). The STAI has been adapted into 72 languages and dialects, and has been cited in more than 15,000 academic studies. To many, the STAI is the premier self-report measurement tool for assessing anxiety. The STAI has become a "gold standard" international assesment tool.

Spielberger's mission to become an international diplomat for psychology was evident in his spending six months in London at Florida State University's Study Center. It is not an overstatement to say that Spielberger went on to becomeone of the most widely traveled – and well recognized – among his peer group. One of his self-stated missions was to "give science away," and he would go on do this by moving psychology into every corner of the globe.

While a consummate traveler, Dr. Spielberger never moved away from his "academic home" once he settled in at the University of South Florida in 1972. As a professor and director of Clinical Training, he facilitated University of South Florida's clinical psychology program obtaining American Psychological Association (APA) accreditation. Dr. Spielberger was also the first recipient of USF's Distinguished Scholar Award in 1973. Recognized as a researcher of the highest caliber, after only 13 years at USF, Spielberger was appointed a Distinguished Research professor of Psychology in 1985. Spielberger founded the USF Center for Research in Behavioral Medicine and Health Psychology in 1977, and served as its director for the next 25 years.

Measurement Genius and Voluminous Scholar

Dr. Spielberger was truly a revolutionary "thought leader" who recognized the incisiveness of his state trait distinction, as he went on to develop additional state trait measures for anger (State Trait Anger Expression Inventory (STAXI)) as well as for personality through the State Trait Personality Inventory (STPI). Charlie produced 16 self-report personality assessment instruments, and his measures are considered to have a unique scientific elegance. Not surprisingly, a Google search using his name produces over 98,000 results.

Not only did Dr. Spielberger revolutionize the field of academic and applied psychology with the state trait distinction, but he also developed innovative factor analytic psychometric methods which contributed to his ability to produce scales with incredible conceptual rigor. For this reason, Spielberger's measures were cherished by academics and clinicians alike, as they were comprehensive yet concise, while capturing the full spectrum of intensity of emotional states. To do this, Charlie was zealously focused on applying the concept of "item intensity specificity" to the self-report item selection process; the idea that particular self report items addressed a particular level of intensity of an emotion. This psychometric concept was first recognized by one of Psychology's early quantitative and measurement gurus, psychologist Dr. Anne Anastasi.

Spielberger's State Trait Anger Expression Inventory (2nd ed.), is arguably one of the most widely used multidimensional self-report measures of anger in the world. In fact, Charlie can be credited with – ahead of his time – recognizing the critical role that anger plays in human functioning well before the world caught up to the vital role anger has gone on to play in now heavily researched phenomena such as mass shootings and workplace violence. Never forgetting his psychodynamic internship or his chemistry training, Spielberger fused these two experiences together as he broke down dynamic emotional processes into their basest components by using factor analysis to uncover empirically revealed processes involved in the experience, expression, and control of anger. Spielberger continued honing the STAXI until its later version (STAXI-2) contained scales for assessing more nuanced anger control mechanisms articulated only theoretically by psychodynamic thinkers before this measure cross culturally validated these fine-grained distinctions.

Known as the first to arrive at the office and last to leave at his Tampa Florida office, graduate students marvelled at his stamina and dedication. Spielberger's 49-page Curriculum Vitae includes six journal associate editorships, five book series editorships, and more than 464 books, chapters, and major articles, as well as 17 grants for conferences and research.

Visionary Who Transcended Boundaries but Was Rooted in Clarity

While many psychologists find comfort in a certain neighborhood of psychology, Charlie was a restless and transcendent spirit. This discomfort with sitting still in any one area, coupled with his incredibly accessible communication style (no doubt faciliated by his practical midwestern academic upbringing at Iowa) allowed him to not only transcend traditional boundaries outlining subfields of psychology, but also resulted in his becoming a Diplomat of Psychology for the public-at-large around the world. Ultimately this resulted

in, when he traveled around the world, his 6′ 2″ physical stature being warmly welcomed as an icon revered for brilliance and statesmanship. Far before the end of his career, he became known as one of our field's Great Thinkers. Frequently, inteviewed around the world by journalists – including the BBC – he would deftly communicate how integral psychology was for understanding such cultural phenomena as road rage. He was also one of the most widely referenced scientists as journalists reported on the far ranging effects of Type A behavior on health.

While the field of psychology continues to spawn new divisions, Charlie's work continues to penetrate boundaries. For example, he was one of behavioral medicine's early visionaries as he constantly recognized vital linkages among psychological and medical variables. His usage of the STAXI and STAXI-2 shined novel light on how anger suppression and control mechanisms critically affected health, leading him to be forefront of scientific discussions regarding relationships among anger, stress, heart disease, and cancer.

While reared and steeped in academic literature, Charlie never became pedantic or spoke in platitudes; he remained grounded in the belief that we psychologists needed to remain understandable to the everyday bystander. As one of Dr. Spelberger's final graduate students, I was always amazed by the hard-edged practicality he brought to every single sentence we wrote. Co-authoring with Charlie meant long hours pouring over drafts until they were perfect; he was a perfectionist par excellence. Going through 50–70 iterations was standard practice. But ask anyone who has read a publication with his esteemed name on it, and you will hear them say that Charlie made complexity simple. His refreshingly clear writing style and chemistry-like breakdown of psychological phenomena was no doubt a reason his measures and theory disseminated deeply into applied business fields such as occupational stress assessment with his Job Stress Survey.

Persistent Leadership, Service, and Recognition

Constantly focused on providing effective leadership, Spieberger became the one hundredth president of the APA, and his presidential motto was "Giving Science Away." He also served as president of eight psychological associations, four APA divisions, and four international associations. Reaching the status of an elite, nationally recognized scientist, he was also chair of the US Council of Scientific Society Presidents (CSSP). Spielberger also became the twenty-fifth president of the first multinational psychological organization, the International Association of Applied Psychology (IAAP), and was founder of IAAP's Assessment Division. With a bottomless tank of energy, in 1980 he brought researchers from 35 countries together and established a new psychological specialization, with the Society for Test Anxiety Research (STAR).

Spielberger was recognized with more than 23 awards and was a Fellow in 14 APA divisions, further testament to the elite magnitude of recognition he achieved. Spielberger's awards included, as follows: *Distinguished Contributions to the International Advancement of Psychology* (APA, 2005); *Life Achievement in the Application of Psychology* (APA, 2003); and *Distinguished Sustained Contributions to Education in Psychology* (APA, 1992). Spielberger was elected a Fellow by the Academy of Behavioral Medicine Research (1984) and a Distinguished Practitioner of Psychology by the National Academies of Practice (1984).

There is no doubt that the voluminous scholarship, passionate collaborativeness, and worldwide diplomacy Charles Donald Spielberger accomplished have collectively produced a landmark of such epic proportion that future generations around the world will continue to view it as a towering achievement. Spielberger, truly one of the The Greats, served psychology with a passion rarely found, yet internationally appreciated. Charlie Spielberger passed away due to congestive heart failure on June 12, 2013, leaving behind his loyal wife, Carol, and son, Nicholas.

Clark, Kenneth and Mamie

Lori A. Barker and Crystal Ukpong

California State Polytechnic University

Kenneth B. Clark and Mamie Phipps Clark were two of the most influential psychologists of the mid-twentieth century. During the turbulent times of Jim Crow, segregation, and the Civil Rights Movement, the Clarks' work played a key role in increasing understanding of racism, its impact on child development, and the dismantling of racist systems and amelioration of their negative effects.

Kenneth B. Clark

Kenneth B. Clark was born in 1914 to a cargo superintendent father and seamstress mother in the Panama Canal Zone. His mother, determined to give her children better education and employment opportunities, relocated the family to New York City where she raised young Kenneth and his sister on her own. His father stayed behind in Panama because he believed the racism in the United States would prevent him from finding a job of equal status (Jones & Pettigrew, 2005; Martin, 1994).

The family settled in Harlem, with its very diverse population. In integrated classrooms, Kenneth noticed teachers held him to the same high standards as his white counterparts. This helped him conclude that all teachers should expect the same performance from their students, and any discrepancies in performance are not attributable to race (Martin, 1994).

In high school, Kenneth had his first direct experiences with racial discrimination. In the New York schools, most Black students were tracked into vocational programs. When Kenneth's mother found this out, she went straight to the school and put a stop to it. She did not immigrate all the way from Panama for her son to be trained as a factory worker. He also qualified for, but was denied, an award for excellence in economics (Jones & Pettigrew, 2005; Martin, 1994).

Kenneth entered Howard University as an undergraduate student, intending to study medicine. However, he took a psychology class with Francis Sumner, the first African American to receive a doctorate in psychology, and was fascinated with the idea of

understanding the complexities of human behavior, such as racism. After graduating with his bachelor's, Kenneth continued to work with Sumner, completing his master's in 1936 (Martin, 1994).

Kenneth was encouraged by his professors to pursue a PhD and was accepted into the doctoral program at Columbia University, becoming the first African American to receive a PhD in psychology from that institution in 1940. Post-degree, Kenneth taught briefly at Hampton Institute, and then became the first African American faculty member at City College of New York in 1942 and full, tenured professor by 1960 (Martin, 1994).

Much of Kenneth's work centered on the effects of racism in education. Research conducted with his wife was very influential in the 1954 Supreme Court ruling in *Brown vs. the Board of Education* to end school segregation. Despite this, schools across the United States remained largely segregated. In 1962, with the support of federal funds, Kenneth created the Harlem Youth Opportunities Unlimited (HARYOU) whose mission was to study and develop strategies for decreasing juvenile delinquency. As chair of HARYOU, Kenneth sought to overhaul the public education system in Harlem with an aggressive agenda including increased integration, improved reading skills, stricter review of teacher performance, and local community participation. HARYOU produced a 620-page report detailing these recommendations; however, few of these recommendations were implemented due to strong political opposition. Nonetheless, HARYOU became known as the first community-action program and a model for future endeavors. Kenneth expounded on his experiences with HARYOU in his best known book, *Dark Ghetto: Dilemmas of Social Power* (1965). Other books by Kenneth Clark include, *Prejudice and Your Child* (1955), *A Possible Reality* (1972), and *Pathos of Power* (1973).

In 1967, Kenneth founded the Metropolitan Applied Research Center (MARC), which focused on identifying and solving the problems of the urban poor. In 1970, the Washington, DC, school board invited MARC to design a new educational program for their students, most of whom were poor and Black. Kenneth based his reforms for education in Washington, DC, on ideas from HARYOU, but again ran into political opposition when the superintendent of schools challenged Kenneth's central hypothesis that ghetto children could be held to the same standards as "normal" children (Martin, 1994).

Despite these setbacks, Kenneth remained committed throughout his career to the idea of integrated education and the need for radical reforms in the educational system. In the 1980s, he lamented over the fact that school systems in the United States continued to fail to meet the needs of poor Black students, and by the 1990s expressed doubt that things would ever change (Martin, 1994).

Kenneth pioneered many "firsts." Besides those mentioned above, Kenneth was the first African American to join the New York State Board of Regents, and the first African American president of the Society for the Psychological Study of Social Issues, and the APA (Jones & Pettigrew, 2005; Martin, 1994). As president of APA from 1970–1971, Clark worked hard to increase the organization's sense of social responsibility. He arranged for Martin Luther King Jr. to address APA officials, met with leaders of the Association of Black Psychologists, worked to diversify the ranks of graduate students, established the Board of Ethical and Social Responsibility, and a task force on the status of women (Jones & Pettigrew, 2005).

Mamie Phipps Clark

Mamie Phipps was born in 1917 in Hot Springs, Arkansas. Her father, a native of St. Kitts in the British West Indies, was a physician, and her mother assisted in her father's practice. Growing up, Mamie attended segregated schools. She received a scholarship to attend Howard University where she initially majored in mathematics and physics (Warren, 1999). However, she became disenchanted with the unenthusiastic attitude of her male professors. When she met Kenneth, who was already working on his masters, he convinced her to study psychology. The two married during Mamie's senior year (Butler, 2016; Jones & Pettigrew, 2005; Lal, 2002; Warren, 1999).

After graduating from Howard in 1938, Mamie worked that summer as a secretary for the law firm of William Houston where she was impressed with the civil rights work of attorneys like Thurgood Marshall and William Hastie (Butler, 2016; Lal, 2002). That fall, she began the master's program at Howard. Her thesis, titled "The Development of Consciousness of Self in Negro Pre-School Children," included the famous doll experiment (Clark & Clark, 1939a) in which African American children were presented with black and white dolls and asked a series of questions, such as which doll was pretty, nice, and a desirable playmate. She found that African American children consistently attributed more positive traits to the white dolls and negative ones to the black dolls. The Clarks concluded that the racism, oppression, and discrimination experienced by Black children in White America led to lower self-esteem and self-image. This research was central to the *Brown vs. Board of Education* Supreme Court decision, but also linked two broader, emerging fields of study – racial prejudice and child development (Butler, 2016; Guthrie, 1990; Lal, 2002; Warren, 1999).

Mamie went on to the doctoral program at Columbia University, the second African American (after her husband) to do so. She worked with Dr. Henry Garrett, who made it clear he believed Blacks and Whites had differing mental abilities and supported segregated education. He also believed her PhD was simply preparing her to work as a high school teacher for Blacks in the South. Nevertheless, Mamie completed her PhD in 1943 (Butler, 2016; Warren, 1999).

Mamie soon realized that employment was almost impossible to find as an African American woman with a PhD in psychology. It broke her heart to see jobs given to less qualified White counterparts. Between 1944 and 1946, she worked as a data analyst for the American Public Health Association and as a research psychologist with the US Armed Forces Institute, but felt dissatisfied with both these positions (Butler, 2016; Lal, 2002; Warren, 1999).

In 1946, Mamie obtained a position at the Riverdale Home for Children, working with Black, homeless girls. She became disturbed when she noticed White children had access to a wide array of psychological and psychiatric services, but not Blacks. She pushed for social service agencies to provide these services to Black children, to no avail (Butler, 2016; Jones & Pettigrew, 2005; Lal, 2002; Warren, 1999).

Mamie continued to focus on issues facing minority youth as trustee for several influential organizations, including Teachers' College at Columbia University, Mount Sinai Medical Center, the New York Mission Society, the New York Public Library, the Phelps

Stokes Fund, the Museum of Modern Art, and the American Broadcasting Company. She also participated in several advisory groups, such as HARYOU and the National Head Start Programming Committee (Butler, 2016; Warren, 1999).

Despite facing racism and sexism throughout her career, Mamie received several awards, including distinguished alumni awards from Howard and Columbia, honorary doctorate degrees from William College and Pratt Institute, and the prestigious fellowship award from the American Association of University Women (Guthrie, 1990; Warren, 1999). While her work helped move forward educational equity for minority youth, and the development and provision of psychological services for this population, until her death she believed the field of psychology had not done enough for the betterment of society (Warren, 1999).

A Power Couple

While both of the Clarks had an impressive record of individual achievements, they also made significant contributions together. Between 1939 and 1950, the Clarks published five articles based on the famous doll experiment (Clark & Clark, 1939a, 1939b, 1940, 1947, 1950; Butler, 2016; Martin, 1994). This research played a critical role in the legal battle to end school segregation, which culminated in the landmark Supreme Court decision in *Brown vs. the Board of Education*. Both Clarks served as expert witnesses in this case, which garnered recognition far beyond the field of social psychology (Keppel, 2002; Pickren & Tomes, 2002), but with more credit going to Kenneth than Mamie (Lal, 2002; Warren, 1999).

The Clarks carried a special burden for providing quality education and psychological services to minority youth. After Mamie's experiences working with homeless Black girls at Riverdale and her unsuccessful efforts to obtain social services for this group, the couple decided to do it themselves. They founded the Northside Center for Child Development (formerly known as the Northside Testing and Consultation Center). The center was the first of its kind to offer psychological and casework services to Harlem families. The center also conducted research on racial biases in education which provided evidence that the issues faced by minority children are primarily due to environmental conditions, not individual psychopathology. Mamie served as executive director from 1946–1979 (Butler, 2016), and Kenneth as the research director from 1956–1966 (Warren, 1999). They initially funded the center with money from Mamie's father, and staffed it with volunteer psychologists, psychiatrists, and social workers. At first, members of the community were fearful of the stigma associated with seeking psychological services. However, the center gained recognition after evaluating and advocating for African American students wrongfully placed in special education classes (Jones & Pettigrew, 2005; Lal, 2002; Warren, 1999). The center grew to a full-service agency providing psychological and psychoeducational assessments, psychological consultations for behavioral and emotional problems, vocational guidance, and parent training (Lal, 2002; Markowitz & Rosner, 2013).

After Kenneth retired from City College in 1975, he, Mamie, and their two children – Kate (born in 1940) and Hilton (born in 1943) – founded Kenneth, Phipps, Kenneth, & Harris, Inc., a consulting firm purposed to help large companies design and implement minority

hiring programs. Some of their clients included AT&T, Chemical Bank, and Consolidated Edison (Martin, 1994).

Mamie Phipps Clark died in 1983 at the age of 66. Kenneth Bancroft Clark died in 2005 at the age of 91. Although not all of their hopes and dreams were realized due to racism, sexism, and political and community resistance, Kenneth and Mamie Clark remained committed to improving educational opportunities and psychological services for poor and minorities. Their contributions to psychology and society cannot be denied and will forever be appreciated.

Helms, Janet E.

Donelda A. Cook

Loyola University Maryland

Janet E. Helms, is a noted counseling psychologist who, since the mid-1970s, has contributed significantly to applied research and cross-cultural considerations in theory, measurement, and application of racial identity (RI) theory. Born in Kansas City, Missouri, Helms earned BA and MA degrees in psychology from the University of Missouri-Kansas City, and a PhD degree in psychology, with specialization in counseling psychology, from Iowa State University. As a Black student attending a predominantly White high school, Helms demonstrated strong aptitude for mathematics, love of reading, award winning writing, and developed keen awareness and personal resistance to devaluing racial experiences with White teachers and peers. These combined academic and personal strengths as a high school student, serve as a foundation for Helms's influential contributions to the development of racial identity models for people from a variety of racial and ethnic backgrounds, corresponding scale development (e.g. Black Racial Identity Attitude Scale, People of Color Racial Identity Attitude Scale, White Racial Identity Attitude Scale), and a substantial body of research.

As an endowed chair, the Augustus Long Professor in Measurement and Assessment, in the Department of Counseling, Developmental, and Educational Psychology at Boston College, Helms has extended her expertise in applied research and assessment of racial identity to social justice issues such as, racial group conflicts on college campuses, cultural factors in research on mental health and medical health racial disparities, and integrating race and culture in teaching, law, and public policy. Helms's scholarship and research on Black and White racial identity attitudes has inspired innumerable graduate students of various racial and ethnic groups (from graduate programs throughout the nation and internationally) to apply racial identity attitudes in their theses, dissertations, and subsequent faculty research programs, on topics related to counseling and psychotherapy processes, personality development, mental health functioning, clinical supervision, family and group interactions, and a variety of social systems. As founding director of the Institute for the Study and Promotion of Race and Culture (ISPRC) at Boston College, Helms has annually hosted the *Diversity Challenge Conference,* which convenes national and international

participants sharing race and cultural theories, research, practices, and public policies to promote increased understanding of the meaning of race and culture in today's society, and to address the societal conflicts associated with race or culture in practical settings and systems.

Racial Identity

Helms's racial identity attitude scales measure individuals' internalization of their perceived racial socialization experiences of oppression or privilege that pertain to the individual's racial group. To date (2015), Helms has published five books, 17 book chapters, over 65 refereed journal articles, and four international conference keynote presentations on racial identity theories, measurement, and applications. Helms's racial identity models represent individuals' attitudes, thoughts, feelings, and behaviors toward one's self and one's own racial group, and toward members of the dominant or other non-dominant racial groups. Helms's Black and People of Color racial identity models expanded on the formulations of William Cross's Black Racial Identity and Atkinson, Morten, and Sue's Minority Identity Development theories. According to Helms's models, African Americans, Latino/Latina Americans, Asian/Pacific Islander Americans, and Indigenous or Native Americans (ALANA), and related immigrant groups' (RIGS), racial identity development is a process of abandoning internalized racism or socialized negative conceptions of one's racial group to develop affirming attitudes about self and one's own racial group. The White racial identity model describes processes by which White individuals overcome the internalized belief that they are superior to other racial groups and come to recognize their privileged status and reject the various manifestations of racism.

In 1984, Helms first published her White racial identity development theory in *The Counseling Psychologist* in a seminal article, "Toward a theoretical explanation of the effects of race on counseling: A Black and White model." Helms recognized the one-sided focus in racial psychology research of the 1970s and early 1980s on Blacks' and other People of Color's psychological reactions to societal oppression and detrimental effects of racism, and the absence of research examining the impact of racial superiority beliefs, unearned privilege, and discriminatory actions on the psychological development of White individuals. The early version of Helms's theory was consistent with scholarly theorizing of that time, that racial identity development was a linear stage-wise process. She theorized that White individuals potentially develop through five stages of varying complexity (i.e. Contact, Disintegration, Reintegration, Pseudo-Independence, and Autonomy) as they increase self-awareness in interactions with Blacks or People of Color. The terminology of "stages" did not accurately reflect the idea that as individuals experience racist events in various aspects of their lives, their reactions might be characterized by more than one stage at a time. Therefore, as a result of empirical measurement studies, Helms modified her theory by replacing the concept of racial identity stages of development to racial identity statuses (e.g. underlying psychological dynamics of individuals' racial development) or schemas (e.g. measurable aspects of the individual's racial identity development). Schemas or measurable aspects of each White racial identity schema are: *Contact* (no consciousness about race, passive acceptance of societal norms for distribution of resources), *Disintegration* (confusion

concerning commitment to White racial group and ambivalence about what it means to be White), *Reintegration* (idealization of White racial group and adherence to external standards of White entitlement and perceptions of other racial groups), *Pseudo-Independence* ("good-bad" dichotomy of racial groups and belief in bringing other racial groups up to White standards), *Immersion/Emersion* (questioning, analyzing, and comparing White racial group status to others, and awareness that Whites must abandon racism), *Autonomy* (self-affirmation of White identity without standard of superiority over other racial groups). Helms proposes overlapping use of more than one schema at a time.

Helms's White Racial Identity Development model has been prominent in race and culture literature in the counseling psychology field. A review of the literature reveals empirical studies utilizing the White Racial Identity Attitude Scale (WRIAS) to measure personality characteristics, racial identity characteristics of counselors or therapists-in-training, applications to counseling interventions, teaching about racial identity in classroom settings, supervision and training, organizational climate, schools, and families. Additional publications include studies of psychometric properties of the WRIAS, commentaries, critiques, and rebuttals of the White Racial Identity Development theory or measurement, as well as new theories based on Helms's theory and revisions of her theory.

Testing and Assessment

Helms has used her expertise in tests and measurement to study cultural and contextual factors, such as racial identity, socio economic status, and chronic experiences of systemic racial discrimination, in assessment outcomes in high stakes cognitive abilities testing. She has advocated for the study of individual responses, instead of studying differences between- and within racial groups, when interpreting racial identity data and standardized testing. Helms developed the individual-differences (HID) fairness model as a method for quantifying the effects of racial and cultural variables on African Americans, Latino/as, Asian Americans, and Native Americans (ALANAs) as compared to White test takers' scores on tests of cognitive abilities. The HID fairness model identifies the source of fairness or unfairness in the interactions between individual test takers' internalized racial experiences, experiences of discrimination in environmental socialization and the testing process. Helms proposes that if the aforementioned factors were eliminated from test scores, it would reduce test-score disparities between Whites and ALANA individuals on cognitive abilities tests that are frequently used to evaluate, diagnose, select, or promote individuals in various settings. Since 1992, Helms has published 13 refereed journal articles and five book chapters related to racial bias and racial and cultural factors in standardized testing.

Distinguished Mentoring, Awards, and Service in Professional Organizations

Throughout Janet E. Helms's academic career, advising and mentoring graduate students has been a hallmark of her professional commitment, identity, and reputation. Helms began her career in academia at Washington State University in Pullman (1975–1977)

followed by Southern Illinois University–Carbondale (1977–1981) where she was first tenured and promoted. From 1981–2000, Helms moved through the ranks of academia to full professor at the University of Maryland-College Park, and, in 2000, moved to Boston College. Throughout her tenure at each institution, Helms has established a "familial network" of graduate students who found an advisor and mentor who taught, empowered, and helped them achieve their desires in adapting psychology to their racial and cultural perspectives in both research and practice, including White students dedicated to social and racial justice in psychology. Furthermore, Helms serves as mentor to a host of graduate students from other programs throughout the nation. She fosters a natural bond among the students she mentors, whereby they support one another as part of "the Janet Helms' family." In 1991, the Columbia Teachers' College Annual Cross-Cultural Roundtable honored Helms as the first recipient of an award in her name, the *Janet E. Helms Award for Scholarship and Research Mentoring*, which is awarded annually to the person who best exemplifies Helms's accomplishments in training culture-focused researchers.

Additional distinguished awards received by Helms include: American Psychological Association (APA) Society for Psychological Study of Culture, Ethnicity and Race 1999 Distinguished Career Contributions to Research Award; the APA Society of Counseling Psychology's highest research award, the 2002 Leona Tyler Award in recognition of an outstanding research career; the 2006 APA's Distinguished Contributions to Education and Training in Psychology Award; the 2007 Association of Black Psychologists' Distinguished Psychologist Award; the 2008 APA Award for Distinguished Contributions to Research in Public Policy; the Distinguished Elder Award at the 2009 APA National Multicultural Conference and Summit; the 2011 Elizabeth Hurlock Beckman National Honor Award that Recognizes Those Who Have Inspired Students to Change the World, Gail McKnight Beckman Trust; and the APA Society of Counseling Psychology 2015 Elder Recognition Award for Distinguished Contributions to Counseling Psychology. Helms has also been appointed Fellow in three APA divisions: 1987 Society of Counseling Psychology (Division 17), 1988 Society for Psychological Study of Culture, Ethnicity and Race (Division 45), 2013 Society for the Psychology of Women (Division 35), and Honorary Degree recipient, Doctor of Science, Honoris Causa, The Chicago School of Professional Psychology, July 2013.

Helms has served in professional organizations through participation on multiple journal editorial boards and a host of leadership positions in Divisions 17, 45, and 35 of APA. She served on five APA journal editorial boards, including associate editor of *Assessment,* and the editorial board member of *Journal of Counseling Psychology, Journal of Multicultural Counseling and Development, and* Council of Elders *Cultural Diversity & Ethnic Minority Psychology*. Her most notable leadership positions in APA include president-elect, 2008–2009 president, and past-president of Division 17, one three-year term on the executive board of Division 45, four three-year terms on the executive board of Division 17, two three-year terms as APA Council representative (Representing Division 17), secretary Division 17, member of the APA Committee on Structure and Function of Council, member of the APA Committee on Testing and Assessment, APA's representative to the Joint Committee on Psychological and Educational Testing, and co-chair of the Joint Committee on Psychological and Educational Testing.

Hofstede Geert

Patricia Arredondo

Arredondo Advisory Group

Born in Haarlem, Netherlands on October 2, 1928, Gerard (Geert) Hendrik Hofstede was an individual who would become an eminent scholar in cultural studies, cultural mindset, and behaviors, and cross-cultural engagement in organizations (Hofstede, 2010). Dr. Hofstede was raised in the Netherlands and attended schools in The Hague and Apeldoorn west of Amsterdam. He graduated from Delft Technical College in 1953 with a M.Sc. in mechanical engineering. His studies also included various internships, such as a voyage to Indonesia, perhaps initiating his global interests.

Upon graduation, he served in the Dutch military for two years and then proceeded to work in a variety of industry sectors in the Netherlands (Hofstede, 2010). It was during his 10 years with industrial firms that Hofstede's interest in the social sciences was ignited. He began a doctoral program in social psychology at Groningen University in northern Holland and simultaneously began to work part-time for IBM (1955–1965). With IBM, he held positions in management training and personnel and founded the Personnel Research Department. He was awarded a PhD, cum laude in 1967. The title of his thesis was "The Game of Budget Control."

The basis for his initial, most notable contribution regarding the cultural mindset arose from his work in the first international survey conducted by IBM in 1966 (Hofstede, 2010). The survey was designed to study the values of IBM employees globally. From survey findings, Hofstede noticed patterns and trends, particularly the similarities and differences of values and opinions among nations and the sectors from which these differences emerged (Hofstede, 2010). The seed was planted, and Hofstede continued his journey in the arena in which he had greatest passion and curiosity – the cultural mindset or *software of the mind* (1991).

Context and Culture as Starting Points

Hofstede is widely known for his identification of cultural dimensions across 50 nations and within identity sectors (i.e. gender, geographical location), which emerged from

the IBM study (Hofstede, 2010). In his analysis of IBM data, Hofstede uncovered contextual information about how socialization in a country and culture may influence mindset (i.e. cognitive processes) and values. He defines culture as a "collective programming of the mind distinguishing the members of one group or category of people from another" (Hofstede, Hofstede, & Minkov, 2010, p. 6). He posits that we acquire our *societal* cultures from when and where we are born, and most of the cognitive programming is developed during childhood; according to Hofstede, this is how culture is learned. He goes on to say that over time culture may change because of geographic changes, or major life events, and as such, individuals adapt to the cultural changes. There are numerous interchangeable terms used to discuss his model, including cultural levels, national cultural values, dimensions of national values, and identity sectors.

Cultural Levels

It is important to consider the concept of cultural levels because they provide explanations on how differences occur within nations regarding the domination of national values that will be discussed in the next section. The prominent cultural levels identified by Hofstede (1991) include: the national level, regional and/or ethnic and/or religious and/or linguistic affiliation level, organizational level, generational level, gender level, and a social class level. The "programming" necessary for these levels may or may not be in agreement, because these levels also represent variables that may be oppositional. Two such examples are religious and gender socialization. Thus, these levels cannot be seen as mutually exclusive. The programming of each level may create conflict that may impact the predicted behavior of an individual. A person may be expected to respond in a particular way because of others' assumptions about their cultural affiliation, but their behavior may be contradictory. For example, older Latino men are considered more conservative and protective of their daughters. When they demonstrate more pro-feminist behavior in support of their daughters' independence, this may be confusing to someone who holds a stereotyped view of Latino men. Individuals of Muslim background hold religious values and practices regarding prayer at prescribed times. This may be questioned in some work environments in the same nation in companies that are not open to Muslim religious practices.

Throughout these cultural levels, cultural differences appear through symbols, heroes, rituals, and values. These elements are considered to make up the "onion model," with symbols being the outer later and most superficial manifestation, and values being the core. Symbols are defined as "words, gestures, pictures or objects that carry a particular meaning and which are primarily recognized by those who share the same culture" (Hofstede et al., 2010, p. 8). Sports images are one example. In most countries, soccer is the national sport; in the United States, it is either baseball or football. Another example is the use of images depicting snow on standardized tests as these have often been confusing to children who grew up in tropical countries.

National Cultural Dimensions, Values, or Indexes

Hofstede examined cultures based on four dimensions or indexes: power distance (high to low), uncertainty avoidance (high to low), collectivism versus individualism, and femininity versus masculinity. Later, in collaboration with other researchers, Hofstede added a fifth and sixth dimension: long-term orientation and indulgence versus restraint.

Each dimension provides insight into how national societies are organized structurally and how they deal with and place value or prioritization on certain practices. For instance, Asian countries are more collectivistic and male-led. These demonstrate the values of masculinity and collectivism. "Problem" areas may emerge because of globalization and the education of women for new work opportunities. Furthermore, there is an interactional dynamic among the dimensions. For example, Hofstede conceptualized the dimension of uncertainty avoidance as a method to cope with uncertainty or unpredictability. Persons from predominantly an individualistic mindset – who presume a greater sense of control and autonomy will likely be at variance from those in collectivistic societies. The same goes for individuals from societies that are masculine in their value structure. Hofstede suggests that these dimensions serve a purpose for a given society because they may be invoked as normative in times of discord. The dimensions will be discussed in brief.

Individualism Versus Collectivism Index

I/we/they are terms used to suggest the dimensions of individualism (I) versus collectivism (we/they) that manifest in different nations. Nonindustrial countries, ones highly dependent on agriculture, are generally collectivistic in structure. That is, there is greater interdependence among family and community members to achieve shared goals. Of course, there will be intracultural differences. For example, families in rural communities in Mexico, China, or India may demonstrate more collectivistic behaviors while corporate employees in metropolitan areas in these countries are socialized to be more individualistic per corporate organizational structures and goals. At the same time, corporate-like organizations across the world do not all behave similarly as the prevailing national or nation cultural mindset/worldview will influence culture-specific norms and behavior in an organization. Some firms will be more hierarchical and stress individual performance while others will emphasize a team approach. Similarly, organizations, like families, can be collectivistic and interdependent while still promoting individual performance. The United States is considered the prototypical example of an individualistic culture, built on historical roots by founders who advanced thinking to suggest that success occurs by "pulling oneself up by one's bootstraps." One example that persists in the United States is misunderstandings of the culture of American Indian tribes. By definition, *tribe* suggests collectivistic models.

Another fundamental premise in an individualistic culture is competition and winning at all costs. Again, this mindset is not one inclusive of women, persons of color, low socioeconomic status groups, and individuals not networked through social capital. For this dimension, individualistic Americans are seen as braggarts compared to the Dutch, according to Hofstede.

There are many other examples of the I/we/they dimension. There is the power of the group in organizations or professional societies. Here, members generally ascribe to professional standards or ethics. Not doing so may mean expulsion. Collectivistic societies, perhaps those led by nondemocratic leaders, also have ways of controlling people's behavior, such as arresting individuals with differing views.

Femininity Versus Masculinity Index

He, she, and *we* are used to discuss this dimension. According to Hofstede (1980), masculinity is culture-bound universally, and most countries or nations are high in the masculinity value. "Gender roles" is considered a modern term to describe the qualities and/or characteristics that are stereotypically assigned to gender. Gender roles modeled by parents contribute to the mental software that programs children's understanding of gender. Globally, socialization prioritizes men over women with the latter continuing to be seen in roles of service and nurturance, and the former in roles of power and authority. "Gender" qualities are learned very early in mostly unconscious ways. For example, women are expected to be caring and nurturing, and this behavior is even desirable in the workplace. Women managers, it is reported, are preferred to male managers because they are more understanding and better listeners. Generally, women are taught not to be first or to take the lead because this role belongs to men.

Power Distance Index (High to Low)

Power distance explores human inequality in various cultures. It is defined as "the extent to which the less powerful members of institutions and organizations expect and accept that power is distributed unequally" (Hofstede, 2005, p. 3). Hofstede proposes a low and high power distance index for this dimension. High power distance is reflected in the behavior of "less powerful" members of society, or the "followers" of those in power. A low degree of power distance suggests that the society believes that inequality is incorrect and attempts to minimize it. When a high degree of power distance is present in a society, it suggests that inequality is considered a normal part of society. Contemporary examples may be in countries where dictatorship prevails with those at the top consistently taking the spoils while the masses go hungry or illiterate.

Uncertainty Avoidance Index

To begin with, this is not risk avoidance, although such behavior may be attributed to high scores on the uncertainty avoidance index. Said individuals and certain sectors of nations (i.e. geographic location, age, and occupation status) may prefer rules and guidelines for behavior. Their tendency is to seek approval and absolute truths, particularly from those in higher power. In countries where there is a prevailing form of governance that is not

democratic, citizens may be accustomed to conducting themselves according to prescribed codes of behavior out of fear or simply because they have always behaved that way.

Individuals with lower scores on this dimension may be more accepting of ambiguity and uncertainty. They may also be open to alternative ways of thinking and not believe there is only one "right" way. For instance, when considering the age sector, it is possible that teens and young adults are more comfortable with ambiguity, engaging in questioning, and not always accepting of one singular response or idea. Retired persons or individuals on a fixed income may have high scores on the uncertainty avoidance index because of perceived and/or real restrictions on their ability to make choices.

Long-term Orientation and Indulgence Versus Restraining

The last two cultural dimensions or indexes emerged from a World Value Survey conducted with 93 samples of national populations. Involved in these samples were commercial pilots, service managers, and statisticians (Minkov, 2007). A long-term orientation describes a mindset that is more open to change and flux. This does not mean that individuals do not plan; rather, they are willing to consider multiple long-term options. Conversely, individuals with a short-term orientation are more inclined to see the past as guiding the future. They cannot imagine, or prefer to not see, variability in life.

Indulgence is highly characteristic of nations with greater productivity and technological advancement, such as the United States. Indulgent individuals may also tend to be more materialistic and have options on how to enjoy life. Those who practice restraint are likely to be from nations where there is a restriction of freedom, fewer choices economically, and a need to endure or go without.

Reflections

Perhaps the intersection of the dimensions or indexes is apparent. It is likely that individuals with high power distance and uncertainty avoidance are also more restrained and have a short-term orientation. As may be apparent, there is a degree of relativity to all of the dimensions as they interact with cultural levels or sectors.

Current Status

Hofstede has been married to his wife Maaike A. van den Hoek since 1955; they have four sons, ten grandchildren, and one great-grandchild (Hofstede, 2010). Hofstede has taught at various institutions, authored over 150 publications, and has received a plethora of honors. He and his son, Gert Jan, a population biologist and social scientist in information management, host a website (www.info@geerthostede.com) addressing international perspectives on culture. Hofstede is Professor Emeritus of Organizational Anthropology and International Management at Maastricht University in the Netherlands (Hofstede, 2010).

Reginald Jones

Steven Stone-Sabali[1] and Kevin Cokley[2]

[1] *The Ohio State University*
[2] *The University of Texas at Austin*

I am Reginald L. Jones, a Fellow of APA and National Chairman of the Association of Black Psychologists. I am here to talk to you briefly about the concerns of Black psychologists and Black people ... Our concern was not with sex in albino rats or research on sharks, goldfish and monkeys. Our concern was not with analyses of Black people and their presumed deficiencies ... Rather, our concern was with strategies for dealing with such problems as racism in education, the psychological assessment of Black people, and the mental health of Black people, employment, welfare and prisons.

Many of us hoped these would be concerns of APA. Yet our survey of the 182-page [APA] convention program revealed that the word racism appeared only once – shared with sexism. A survey of the index of Psychological Abstracts for 1960–1970 revealed that the word racism does not occur. One could conclude from such a survey that this topic is not of much concern to psychologists.

> – A speech delivered after Dr. Reginald Jones and colleagues of the Association of Black Psychologists commandeered the American Psychological Association's Council meeting in 1971.

Far from a sporadic outburst, Dr. Jones' speech at the American Psychological Association's Council meeting in 1971 was one of the many calculated maneuvers to promote social justice and equity within psychology and education. However, prior to becoming a founder of the Association of Black Psychologists, writing the seminal book on Black Psychology, publishing and editing 22 books and 200 articles, and becoming an expert on children with special needs and the psychological experiences of the African American community, Dr. Reginald Lanier Jones was simply known as "Reg" or "Reggie."

He was born on January 21, 1931, raised in the Clearwater and Miami areas of Florida to a family where creativity, success, and perseverance were staples in their bloodline. For instance, his paternal grandfather was one of a few African Americans who owned a business (a hattery) in downtown St. Petersburg, Florida during the 1930s and 1940s. His father,

Moses Jones, though not a high school graduate, independently studied electronics and eventually became a professional musician and inventor. Entrepreneurial and creative propensities were also found in the activities of extended family members, and included printing and distributing poetry, designing women's clothes, and owning a large clothing manufacturing company.

Dr. Jones' mother, Naomi Henry, had a strong influence on the development of the family's critical thinking, introspection, and understanding of societal issues. She incorporated reading into the daily activities of her children. Meal times would often include family discussions about articles from the Black and White newspapers, notable and successful African Americans, and local and national topics that impacted the Black community. Dr. Jones's mother also cultivated the family's critical thinking and reflective skills by providing constructive discipline, nurturance, and expecting her children to act with integrity. A testament to the high functioning household of Dr. Jones' mother is seen through her children's accomplishments: Dr. Jones, a distinguished scholar, researcher, and social justice advocate; his brother Kenneth Johnson, a retired 20 year Navy veteran and electronics specialist; and his sister Sheryl Johnson, an attorney.

In addition to his mother's guidance, Dr. Jones was exposed to various types of people and personalities during his summer stays with his father in the Philadelphia area. Under his father's socialization and experiential teachings, Dr. Jones became more aware of human behavior and interactions, which likely complemented his latter interests in psychology. Altogether, the successful influences within his family's history, in combination with his mother and father's tutelage, would support Dr. Jones throughout his education and career. He graduated third in a class of 165 students from Booker T. Washington high school in Miami, Florida. For his undergraduate studies, Dr. Jones had an academic scholarship to attend Morehouse College to study psychology. Next he completed a clinical psychology master's degree at Wayne State University, and subsequently worked as a military clinical psychologist before pursuing a doctoral degree in School Psychology at The Ohio State University.

Professional Career

Throughout his professional career, Dr. Jones continued to reflect his mother's leadership and his father's creativity. Like his father, Dr. Jones would create (or invent) scholarly literature and academic programs to address the needs in multiple fields such as Psychology, Black Psychology, and Special Education. In addition, like his mother was to his family, Dr. Jones would become a cornerstone in numerous professional organizations and academic programs, where he mentored and guided staff and faculty.

The existence of the field of Black Psychology is indisputably and synonymously associated with Dr. Reginald Jones. In the early 1970s, the unique experiences of African Americans and Africans were largely absent, if not non-existent, in the field of psychology. Dr. Jones would change that by devoting the next 30 years of his life to developing the field of Black Psychology. His journey began by assessing whether the Association of Black Psychology's (ABPsi) membership would be interested in what would become *The Journal of Black Psychology* (later founded in 1974). Dr. Jones also contributed by publishing

multiple resources that established and aided the field of Black Psychology. In 1972, he penned the seminal book on Black Psychology, as well as subsequent editions in 1980, 1991, and 2003. Thereafter, he authored or edited two volumes of the *Sourcebook on the Teaching of Black Psychology* (1978), which contained undergraduate and graduate course outlines, student exercises, psychometric instruments, and videos of leading Black scholars. Other books by Dr. Jones focused on multiple aspects of the Black experience, such as parenting Black youth (Jones, 1999b); the development of Black adolescents (Jones, 1989a); the development of Black adults (Jones, 1989b); culturally specific tests and measurements for Black populations (Jones, 1996), African American psychology (Jones, 1999a); African American identity (Jones, 1998a); and African American mental health (Jones, 1998b). Altogether, Dr. Jones authored more than 200 articles, 22 books, and 28 videotapes.

Not only did Dr. Jones develop a field of literature. He was also heavily involved with several higher education programs. Over the course of a 33-year career, Dr. Jones was a professor at nine institutions. He was Vice Chair of Staff Development at the Ohio State University's psychology department where he oversaw recruitment, appointments, promotions, and terminations within the department. In addition, Dr. Jones held a professorship position at the University of California, Riverside where developed a graduate program in Special Education, created the first doctoral program in Special Education within the University of California system, and eventually became the Department Chair. Shortly after, Dr. Jones became the Director of the University Testing Center at Haile Selassie I University in Addis Ababa, Ethiopia. Notably, he developed the admissions test for entry into the university, which aimed to quell the disproportionately low representation of certain tribal groups.

After his time in Ethiopia, Dr. Jones became a faculty member at Berkeley for the next 17 years. He held many positions of leadership, and was awarded the Berkeley Citation, one of the highest university honors. Towards the end of his career as a psychologist, Dr. Jones became a Distinguished Professor of Psychology and Chair of the Department of Psychology at Hampton University. Alongside Dr. James Victor, he secured a 5 million dollar grant from the US Office of Education to create the Center for Minority Special Education. There, Special Education faculty from of Historically Black Colleges and Universities and institutions with 25% or more students of color, were trained in grantsmanship. Upon expiration of the US Office of Education grant, as the Director of the Career Opportunities in Research Program, Dr. Jones secured a grant from the National Institute of Mental Health (valued greater than a million dollars), to prepare undergraduate students for graduate training in mental health research. Lastly, he also created and ran Cobb & Henry, Publishers, a privately owned book publishing company.

In addition to his work in the field of Black Psychology, Dr. Jones significantly contributed to the field of Special Education by contributing to more than 30 empirical articles, 15 book chapters, and seven books that focused on the social and educational experiences of children with disabilities and ethnic minority children. His research led to the publishing of two significant seminal papers (Jones, 1972; Jones, 1974) about attitudes, labels, and stigmas towards children with special needs and ethic minority children.

Specifically, Dr. Jones' contributions moved the field's tendency to view labels as universally harmful, towards a need to investigate the complexity of the relationship between (a) labels, (b) behavior of able-bodied persons and children with disabilities, and (c) individualized

and person-specific conclusions. By challenging the notion that children with disabilities were members of a homogeneous group who were universally rejected by others, Dr. Jones highlighted the hazards of applying generalizations to groups (i.e. viewing labeling as a universally harmful action to all members in a group), and instead introduced the hierarchal complexity of attitudes, as they relate to disability type. Further, Dr. Jones was able to masterfully identify parallels between the treatment of and conclusions about children with disabilities with the treatment of ethnic minority children, and confronted the perspective that "mainstreaming" children of color should not be universally accepted or rejected. Ultimately, his efforts enriched and shifted the discourse about attitudes towards children with disabilities, the effects of labels, the impacts of mainstreaming, and the intersectionality of children with special needs and ethnicity. Dr. Jones' scholarly contributions in Special Education were so profound that Distinguished Professor Emeritus Donald MacMillan previously stated, "any author reviewing research on attitudes towards various disability groups could not ignore [Dr. Jones'] work without being severely criticized."

Altogether, Dr. Jones' efforts left a profound imprint in the fields of Special Education and Black Psychology and is evidenced through various awards, such as the Ohio State University and the Berkeley Citations for Distinguished Achievement, the Distinguished Psychologist Award from the Association of Black Psychologists, the Award for Outstanding Publications and Service from the Black Caucus of Special Educators of the Council for Exceptional Children, the Education Award from the American Association on Mental Retardation, the J. E. Wallace Wallin Award from the Council for Exceptional Children, the Loetta Hunt Award from the Faculty for Exceptional Education at the Ohio State University, the Distinguished Alumni Award from Wayne State University, and the Norfolk, Virginia Key to the City award.

McIntosh, Peggy

Laurie A. Roades

California State University, Fullerton

Biographical Background

Peggy McIntosh was born in Brooklyn, New York, in 1934 and raised in New Jersey. She grew up wanting to be a teacher and, after earning a degree in English from Radcliffe College, she taught at a private girls' school and later earned a PhD from Harvard (Rothman, 2014; National SEED Project, n.d.). McIntosh co-founded the Rocky Mountain Women's Institute and later began working at the Wellesley College Center for Research on Women (now the Wellesley Centers for Women) in 1979. Formerly an associate director of the Wellesley Centers for Women, she now serves as a senior research scientist and oversees the Gender, Race, and Inclusive Education Project (Wellesley Centers for Women, n.d.). McIntosh founded the Seeking Educational Equity and Diversity (SEED) Project on Inclusive Curriculum in 1986, serving as co-director until 2011 (National SEED Project, n.d.).

Contributions on White Privilege

Personal Awareness

McIntosh's understanding of *privilege* grew out of her own experience as a woman teaching in women's studies in the 1970s and 1980s (McIntosh, 1988, 2015a). She noted that, although some men recognized women experienced disadvantages, they were not willing to accept that, as men, they experienced corresponding privileges (McIntosh, 1988). What struck McIntosh as she reviewed men's participation in feminist seminars about scholarship on women was that these men were both "nice" *and* "oppressive." She says that previously "I felt I had to choose either that they were nice or that they were oppressive" (McIntosh, 2015a, p. 16). She learned from African American colleagues, as well as the Combahee River Collective feminists, that these groups found working with White women

oppressive. This led her to a new understanding: "Niceness has nothing to do with whether or not one is oppressive" (McIntosh, 2015a, p. 17).

McIntosh began to understand that, as a White person, she needed to recognize the privilege she had been granted based on her own skin color and ethnicity. Her seminal 1988 article examined in depth what she described as "an invisible package of unearned assets that I can count on cashing in each day, but about which I was 'meant' to remain oblivious" (p. 2). The metaphor of an invisible and weightless knapsack highlighted both the lack of awareness one could have about such privilege, as well as the ease with which one could draw upon its benefits. McIntosh went on to identify 46 ways in which she experienced skin-color privilege, through common experiences she had come to expect and of which she had been unaware. Examples included: "I can turn on the television or open the front page of the paper and see people of my race widely and positively represented" (#6); "If I declare there is a racial issue at hand, or there isn't a racial issue at hand, my race will lend me more credibility for either position than a person of color will have" (#30); and "I can arrange my activities so that I will never have to experience feelings of rejection owing to my race" (#42) (pp. 4–7).

Discussion of Privilege

McIntosh was clear that the word *privilege* seems too positive for the impact it has, in that it negatively affects both those who have it and those who do not, and is detrimental to society as it serves to maintain oppression and discriminatory systems. She also noted the multiple bases of "interlocking oppressions," and her discussion of privilege extended across numerous experiences and identities (e.g. social and economic class, sexuality, and religion). McIntosh concluded her original 1988 article by questioning whether those with knowledge of their unearned privilege would act to try to decrease such preferential systems.

Throughout the years, McIntosh's consistent message has been that individuals are not personally responsible for the systemic privilege that benefits them. A key point in her discussions is that we are all privileged in some ways and oppressed in others (McIntosh, 2012, 2015a; TEDx, 2012). Privilege is part of a systemic framework that was not created or requested by those who experience it. Such realizations help reduce defensiveness and guilt that can interfere with accepting awareness and engaging in action to combat such a system. While not responsible for the systems into which they are born, individuals *are* responsible for what they do with their privilege to equalize it for others. Rather than being defensive, McIntosh believes individuals who are not burdened with guilt, shamed, and blamed are more likely to openly listen to the experiences of others and consider ways in which they experience privilege in their own lives (McIntosh, 2012). This approach has served as the basis for much of McIntosh's subsequent work.

Leader and Role Model

Peggy McIntosh has been instrumental in identifying and shaping our understanding of "privilege" and, more specifically, our understanding of "White privilege." For many White individuals, she provided a language and a way to understand their unearned privilege

based on skin color. And, for broader audiences, her framework provided the opportunity to examine privilege in their own lives. McIntosh observed that her work on White privilege has had a differing impact on different readers. As she noted, for White readers her work often opened their eyes to ideas they'd never considered. For people of color, it provided support and evidence of what they'd known for years: there is a systemic framework that privileges some based on race (McIntosh, 2015a; Rothman, 2014).

McIntosh recognized that she was neither the first to articulate the concept of White privilege nor to write about it. When asked why she thought her 1988 paper on the topic had made such an impact, she stated, "I think it was because nobody else was writing so personally, and giving such clear examples, drawn from personal experience, which allowed readers to understand this rather complicated subject without feeling *accused*" (Rothman, 2014, para 11).

Moreover, McIntosh has served as a role model for many by sharing her deeply personal experiences of understanding and trying to confront her own privilege. She did so in her initial work on this subject (McIntosh, 1988) and has continued to do so throughout her career (McIntosh, 2015a). In her 2015 chapter *Real-izing Personal and Systemic Privilege*, McIntosh discussed in depth how she came to an understanding of White privilege and a commitment to seeing it and working to address it in her own life. She described a shocking lesson in racism she learned as a young girl from her grandmother. As an adult, she realized White privilege had allowed her not to remember the experience and to distance herself from it. She openly shared how she actively prayed for an understanding of the unearned privilege and advantages she experienced in contrast to her African American colleagues and how the first example came to her in the middle of the night. She noted, "After three months, when the examples stopped coming, a voice in me said, 'Peggy, you should publish this. It is probably the most important work you will do in your life.' And so it has been" (McIntosh, 2015a, p. 19).

In addition to describing and explaining White privilege, McIntosh has also called on those who understand their privilege across any domain to do something about it. She developed the metaphor of a *bank account* that privilege provides (McIntosh, 2009). Although never personally requested, one still has this bank account of privilege and can use it to effect change. In her 2012 TEDx talk, *How Studying Privilege Systems Can Strengthen Compassion*, McIntosh discussed how she has used her own personal "bank account of White privilege to weaken the system of White privilege," noting that it "keeps re-filling because I get the benefit of the doubt [from other White people]." She concluded her talk by saying, "It has been transformative to use … the power I did not know – I was never taught – that I had, in the service of a kinder, fairer, and more compassionate life for everyone."

The SEED Project

Seeking to expand her work and help others apply it more broadly, McIntosh founded the SEED Project on Inclusive Curriculum in 1986 to help K–12 schools, as well as colleges and universities, identify ways to more fully integrate gender and multicultural diversity into their curriculum and to change classroom climates (see www.nationalseedproject.org).

She co-directed the SEED Project with Emily Style for its first 28 years. McIntosh has noted that self-knowledge is crucial for teachers (McIntosh, 2015b). Thus, a key component of the SEED seminars involves *serial testimony* in which participants speak based on their experiences and hear from others in their own words. By 2017, the SEED Project, through national and branch programs, had trained over 2,600 SEED leaders (National SEED Project, n.d.). McIntosh has identified co-leading the National SEED Project as her "main public action project" (McIntosh, 2015a, p. 21).

Other Work

McIntosh's papers on feelings of fraudulence (e.g. McIntosh, 1985) have found ready adherents among academic audiences. In addition, her interactive phases of curricular and personal revision have influenced curricular and organizational changes by many working in academia (McIntosh, 1983).

Legacy of Her Work

McIntosh's writing and training on White privilege remain influential. Perhaps it is not surprising that, although McIntosh's work has been widely applauded by many, her discussion of White privilege and her desire to shape the educational experience have found critics. Even some authors who recognize her many contributions have expressed concern that her discussions, and those who use her work, do not go quite far enough in combating racism. However, McIntosh's conceptualization of privilege has served as the foundation for numerous papers and programs addressing this issue, and for decades she has demonstrated a commitment to using her own privilege in efforts to weaken oppressive privilege systems. In 2012, a special issue of the *Journal of Social Issues* was devoted to examining privilege, with articles throughout noting the impact of her 1988 landmark examination of this topic. McIntosh (2012) herself provided the final commentary and noted the need for further efforts in this arena. McIntosh continues her important work, and her influence continues to shape teaching, research, public discourse, and activism.

Root, Maria Primitiva Paz

Laura S. Brown

Independent Practice, Seattle, WA

Maria P. P. Root has been a leading figure in the development of affirmative models of identity development for mixed-race people. She was born in Manila, the Philippines, daughter of a Filipina mother and a Euro-American father, and immigrated to the United States when she was three years old. The simple facts of the circumstances of her birth became the foundation for a distinguished career in which Dr. Root became the leading psychological scholar of the life experiences of people of mixed-race heritage. Dr. Root's work exemplified a capacity for independent scholarship; most of her award-winning work and writing was produced while she was a private practitioner. It also exemplified the concept that one's personal experiences can become the basis for the development of theory that looks outside the box of accepted wisdom to shed new light on previously poorly-understood topics. Before Dr. Root's work, racially mixed people's experiences were often stigmatized, both by the larger culture and by psychology. As a result of her scholarship, the lives, not only of racially mixed people, but of all individuals for whom intersectionalities play an important part in identity, have become illuminated. Dr. Root was a trainer, an educator, and a public speaker on the topics of multiracial families, multiracial identity, cultural competence, trauma, work place harassment, and disordered eating. She lectured around the world, including New Zealand, England, the Netherlands, Canada, and the United States.

After receiving her B.A. from the University of California at Riverside in 1977 Dr. Root attended Claremont University, where she received a master's degree in cognitive psychology in 1979. She then entered the clinical psychology doctoral program at the University of Washington, from which she received her PhD in 1983. Her initial area of both clinical and research focus was the topic of disordered eating. Her first publication, *Bulimia: A Systems Approach to Treatment,* co-authored with her dissertation adviser, the late William Friedrich, and her colleague Patricia Fallon, was the first systemic application of a feminist family systems model to the experiences of bulimic women. Root and Fallon were also among the first researchers to empirically identify a relationship between a history of childhood interpersonal trauma, particularly childhood sexual abuse, and the

development of disordered eating, which they conceptualized as a coping strategy for experiencing control in a violated body. Dr. Root also served as co-editor (with this author) of a foundational volume in the field of feminist therapy, *Diversity and complexity in feminist therapy*, published in 1990. Dr. Root's chapter on what she labeled "insidious traumatization" (Root, 1992) presaged the development of the construct of micro-aggression; she was the first psychological scholar to describe the linkage between target group membership and chronic exposure to low-level traumatic stressors.

After receiving her doctorate, Dr. Root opened a clinical practice focused on adult and adolescent treatment which included working with families and couples. The focuses of that practice included culturally competent practice, life transition issues, trauma, ethnic and racial identity, workplace stress and harassment, and disordered eating.

Additionally, Dr. Root offered psychological evaluations, working as a consultant to several law enforcement departments, with a special focus on screening potential law officers around issues of bias. She also provided expert witness services in forensic settings performing evaluations and offering expert testimony in matters that required cultural competence and/or knowledge of racism or ethnocentrism.

In 1990, Dr. Root spent a year as a visiting scholar at the University of Hawai'i-Manoa. She then served on the faculty of the Department of Ethnic Studies of the University of Washington before returning to her full-time private practice of psychology, although she continued to conduct research as an independent scholar.

In 1992, Dr. Root published the first of her many ground-breaking works in the field of mixed-race identity, *Racially Mixed People in America*. In this book, she began to develop an affirmative narrative for a group of people who had previously been either exoticized or stigmatized because their existence challenged dominant cultural narratives of race as fixed and invariant, and of romantic and familiar relationships across racial borders as transgressive. Root up-ended biased perspectives that portrayed mixed-raced people as marginal, tragic, or pathological. In place of these flawed and racist conceptualizations, she pioneered her Ecological Framework for Identity Development, which argued that for mixed-race people, identity development is neither linear or the same for each mixed-race individual. Her paradigm, which can be found at http://drmariaroot.com/doc/EcologicalFramework.pdf, nested identity development within multiple larger systemic contexts, including regional and generational histories of race and ethnic relationships, family systems, sexual orientation, gender, and social class. Her model was the first truly intersectional paradigm for identity development, proposed decades before the construct of intersectionality became popular, evidence of the visionary nature of her work. Not only did it create an affirmative norm for the experiences of people of mixed heritage, this model also inspired other scholars and theorists of intersectionality.

An additional striking contribution that Root made to theories of mixed-race identity development was her proposal that there are multiple, equally valid trajectories for identity development for people who have intersectional identities. This idea arose from her innovative research on biracial siblings (Root, 1998). Root's provocative finding was that within the same family, different siblings had significantly different trajectories in the development of their racial identities. These five trajectories were: (1) accept identity as assigned by society; (2) identify monoracially (consistent with the rule of hypodescent); (3) identify with multiple racial groups; (4) identify as a new racial group, and (5) create a

symbolic racial identity that is unyoked from phenotype or dominant cultural narratives. By identifying all of these trajectories as equally valid and non-pathological experiences of identity for mixed-race people, Root subverted stereotype and made transparent the diversity and complexity of the lives and identities of people of mixed race.

Root's work has had influence beyond the field of cultural studies, with significant impact on the development of feminist therapy theory and practice and trauma psychology. Because her scholarship was intentionally intersectional and multidisciplinary almost from its inception, her work has inspired scholars and researchers inquiring into the ways in which multiple and intersecting identities affect individuals' understandings of themselves and their relationships to the larger social contexts in which they reside.

Dr. Root retired from the field of psychology in 2014. She currently has a career as a distinguished ceramics and tile artist, a field in which she also wins awards. She lives in Seattle with her husband, Bruce, two cats, and several turtles.

Sue, Derald Wing

Julie Sriken[1] and Kevin Nadal[2]

[1] *Vanderbilt University*
[2] *City University of New York*

Early Experiences and Personal Life

Sue was born in Portland, Oregon, and was the second oldest of six children in a working-class Chinese American family (APA, 2013; Munsey 2006; Parham, 2011). When he was a child, his family moved from Portland's Chinatown to a predominantly White suburb outside of the city. In this neighborhood, his White peers insulted and harassed his brothers and him due to their racial background, the language they spoke at home, and their smaller physical frames (Parham, 2011). His older brother David often had to physically fight with other boys, in order to protect Sue and his younger brother Stanley (Parham, 2011). His teachers and counselors stereotyped him as being good at math and sciences, which Sue viewed as bothersome and insensitive (Parham, 2011). As adolescents, Sue and his brothers had regular discussions on racism, which spurred their interest in psychology and human motivation. Four of the Sue brothers later became psychologists (APA 2013; Munsey, 2006; Parham, 2011).

In the 1970s, Sue met Paulina Wee, a Chinese American student who was completing her teaching credential at University of California Berkeley. Paulina was proud of her racial and ethnic heritage and taught Sue to embrace his cultural identity. They married and raised two children – Derald Paul and Marissa. He has two granddaughters – Carolyn and Juliette.

Career Trajectory

Sue earned his Bachelor of Science degree from Oregon State University in 1965; his Masters of Arts degree in Counseling Psychology from the University of Oregon in 1967; and his PhD in Counseling Psychology also from the University of Oregon in 1969. As a student, Sue noticed that his training relied on the assumptions that all people had goals of independence and individuality, which was at odds with the collectivist goals of his

Chinese upbringing (APA, 2013; Munsey, 2006). He also realized that the field of psychology reflected a bias in favor of White, European culture and did not account for the possibility of cultural differences (Parham, 2011). Because he did not have any mentors who were interested in topics related to multiculturalism, he turned to writings of civil rights activists (Munsey, 2006; Parham, 2011) like Dr. Martin Luther King, Malcolm X, Huey Newton, H. Rap Brown, and Cesar Chavez (Parham, 2011).

In the early 1970s, Sue worked as a counseling psychologist at the Counseling Center of the University of California, Berkeley. He was happy that there was a larger Asian American population on campus, which was much different than his previous experiences in Oregon. He related to many of the Asian American clients with whom he worked in psychotherapy, and he was well known by the Asian American students on campus. He admitted that while he enjoyed counseling, he found the process to be slow. And because he wanted to make change on societal levels, he decided to become a researcher and enter academia. He held positions at Santa Clara University, California State University, Hayward, and Alliant University. He started his position at Teachers College – Columbia University in 2001, where he has been ever since.

At the age of 31, Sue became the youngest journal editor of the *Journal of Counseling and Development* – the flagship journal of the American Counseling Association (formerly known as the American College Personnel Association). He experienced a great amount of backlash during this time – particularly from members who believed that his focus on social justice issues was controversial and overly political (APA, 2013; Parham, 2011). Although there were many members who requested his resignation as editor of the journal, Sue continued his term. However, because he experienced significant distress from his naysayers, he decided against completing a second term.

In 1972, Sue co-founded the Asian American Psychological Association (AAPA) with his brother Stanley, and he served as the founding president. Because of the lack of visibility of Asian Americans in psychology, they formed the AAPA to advocate for the mental health needs of Asian Americans through research, practice, education, and policy. The organization began with a handful of active members in California and grew to a national organization with over 850 members as of 2017 (AAPA, 2017).

Sue published many books, including his first text *The Psychology of Personality* (Sue, 1970), which was followed by *Introductory Psychology* – a co-authored book with Dr. Marvin Schroth (Schroth & Sue, 1976). In 1981, he co-authored Counseling the Culturally Diverse with his brother Dr. David Sue (Sue & Sue, 2015); now in its seventh edition, it has become his most frequently cited and best-known text. In 1996, he co-authored *A Theory of Multicultural Counseling and Therapy* with his colleagues Drs. Allen Ivey and Paul Pedersen (Sue, Ivey, & Pedersen, 1996). Finally, in 2004, with his two brothers David and Stanley, he co-authored *Understanding Abnormal Behavior,* a book that is now in its eleventh edition (Sue, Sue, & Sue, 2015).

Contributions to Multicultural Counseling

The bulk of Sue's research indicated that the techniques and knowledge meant to support psychological health are not universal, but must be understood through cultural lenses.

In the 1970s, Sue's initial research focused on the relationship between Chinese American culture and mental health needs and later expanded to include other Asian Americans. In the 1980s and 1990s, Sue addressed the cultural barriers to providing appropriate mental health services to people of color and advocated for greater cultural competence in counseling. Sue's earliest theoretical models described a tripartite model of multicultural competence – knowledge, awareness, and skills. Sue and many colleagues advocated for standards for competencies and skills in multicultural counseling, which eventually were adopted by the American Counseling Association (Sue, Arredondo, & McDavis, 1992) and the American Psychological Association (2003).

Contributions to Anti-Racism Research

Sue's two major contributions to anti-racism research are his work on microaggressions and racial discourses (APA, 2013; Parham, 2011). Because the US civil rights movement changed the way that racism is expressed and recognized, he proposed that racism manifests differently and that people have difficulty discussing issues related to race.

Microaggressions

Sue is considered the most prolific and influential researcher on microaggressions, or subtle forms of discrimination. Based on the initial coining of the term by psychiatrist Chester Pierce in 1970, Sue defined microaggressions as banal individual-level interactions which subtly invalidate, subtly demean, or explicitly insult individuals because of their social group membership. In his 2007 paper, *Racial Microaggressions in Everyday Life: Implications for Clinical Practice*, Sue and colleagues proposed a classification system for microaggressions. This taxonomy was a significant advance because it allowed clinicians to recognize microaggressive experiences within psychotherapy and in everyday life (Sue et al., 2007). Within 10 years, there were over 150 publications written on racial microaggressions (APA, n.d), with a comparable number of papers written on microaggressions toward women, people with disabilities, religious minority groups, and lesbian, gay, bisexual, transgender, and queer people.

Racial Discourses

During the mid-1990s and through the 2000s, Sue began to suggest best practices for discussing racial discrimination and how to support organizational changes toward multicultural inclusion. He described how racism is central to Whiteness and to the history of the United States, resulting in his book *Overcoming Our Racism: The Journey to Liberation* (Sue, 2003). He also noticed that discussing race relations in the United States is emotionally and psychologically taxing because the topic violates several rules of social etiquette. His research team began to examine difficult dialogues on race, which led to his most recent text – *Race Talk and the Conspiracy of Silence: Understanding and Facilitating Difficult Dialogues on Race* (Sue, 2015).

Criticisms

In his early career, Sue encountered resistance from psychologists who argued his research on cultural competency, racism, and social justice was irrational and based on his personal political agenda (APA, 2013; Munsey, 2006). Other researchers criticized Sue's theories because it is seemingly impossible to scientifically prove or measure (Sue, 2017; Sue, Capodilupo, Nadal, & Torino, 2008). However, Sue argued that the lack of falsifiability has not prevented many in psychology from accepting other theories (e.g. psychodynamic theories by Freud) and that denying the reality of systemic and interpersonal racism is a microaggression in itself (Sue et al., 2008).

Some journalists and psychologists have critiqued microaggressions theory as being merely trivial slights rather than more harmful forms of racism (Sue et al., 2008). Some have claimed that people who experience microaggressions are overly sensitive to simple rudeness and that microaggression theorists encourage a culture of self-victimization in order to manipulate benefits from others (Sue et al., 2008). Sue has defended that while some microaggressive incidents may be not cause great harm in any singular instance, it is the chronic near-constant experience of these acts that lead to psychological harm (Sue et al., 2008). Further, Sue has claimed that acknowledging microaggressions does not foster a sense of psychological weakness but actually demonstrates the psychological resilience required to tolerate such unending discrimination (Sue et al., 2008).

Future Plans

While Sue's extensive research and advocacy on multicultural competence and microaggressions has resulted in increased training, education, and awareness of social justice issues, Sue has cited many important directions for the field of psychology. First, mental health professionals must learn to identify and address their biases that they hold against other groups, in order to foster more meaningful relationships. Second, institutions should recognize how they perpetuate systemic discrimination in their practices and instill policy changes to be more inclusive of all cultural groups. Finally, the field of psychology must foster social justice as a core concern because social injustices affect all aspects of an individual's mental health.

Triandis, Harry C

Sharon G. Goto and Kevin Wei

Pomona College

Dr. Harry C. Triandis, baptized Charalambos Theodor, was born in Patras, Greece, on October 16, 1926. As described in his autobiography (Triandis, 2015), his great grandfather was Nicholaos Triandis who established the Triandis and Sons company. This prominent family is well documented in "The History of Patras." Harry spent a happy childhood with French and German governesses in Thessaloniki, Chalandri, and Athens. He attended a French international high school until the German occupation of Athens when his family moved to the island of Corfu, where he spent his formative years. Here, he learned the value of austerity and always thereafter appreciated the saying, "A person who has few needs cannot have a greater good." Of his high school studies, he writes "It was fun studying physics, psychology, politics, astronomy, and many other subjects. I liked psychology especially, but I did not think that I could make a living in that field." After the war, the family returned to Athens and he continued his studies in engineering at Athens Polytechnic, where he also honed his lifelong appreciation of music. In 1948, he attended McGill University in Canada and then accepted his first job at Proctor and Gamble. As he worked, he received a Master of Commerce degree (MBA) from the University of Toronto, where he took a "Human Relations in Industry" course taught by Joyner, a student of Carl Rogers. Encouraged by psychologists including Lilian Gilbreth, he pursued and completed his doctoral studies with William Lambert in three years at Cornell University. During this time, his interest in cross-cultural comparisons emerged through working with Charles Osgood on the structure of affective meaning in Greece (Triandis & Osgood, 1958) and investigating the universal structure of emotions (Triandis & Lambert, 1958). He wrote a 500-page dissertation on communication that resulted in several publications in the *Journal of Applied Psychology* and *Human Relations*. In 1958, upon the recommendation of Osgood, he was offered a job at the University of Illinois, sight unseen. Dr. Triandis accepted, happily spending the rest of his career in Illinois, despite several competing offers from other universities. There, he lived with his wife, Pola, until retirement. Dr. Triandis passed away in 2019. They have a daughter, Louisa, and two grandchildren.

As in all things, Harry Triandis was thorough, thoughtful, and prepared. His professional accomplishments were many as detailed in his self-published obituary (Triandis, 2015), partially quoted here:

> He came to Illinois in 1958, and was especially devoted to WILL [*sic* local station] and the Krannert Center for the Performing Arts because he loved classical music. He became professor emeritus of psychology at the University of Illinois in 1997. He was named a University of Illinois Scholar in 1987. His field of specialization was cross-cultural psychology. After publishing the 6-volume Handbook of Cross-Cultural Psychology, some of his colleagues named him "father" of this new branch of psychology. His research required collaboration with colleagues from different cultures so he circled the globe four times and spent many months in other cultures. He lectured in about 40 countries on all inhabited continents.

He was a fellow of the American Association for the Advancement of Science, five divisions of the American Psychological Association (APA), a fellow of the Association for Psychological Science (APS), and a fellow of the International Association for Cross-Cultural Psychology, which administers the Harry and Pola Triandis Doctoral Thesis Award that is given every two years for the best dissertation in the field. He received awards from the Interamerican Society of Psychology, from the APA (the Centennial Citation, "for significant contribution to the establishment of Cross-Cultural Psychology as a distinct discipline," and the Distinguished Contributions to International Psychology Award). The APS named him James Cattell Fellow. The International Division of the APA named him Distinguished International Psychologist of the Year 2002. The Society for the Psychological Study of Social Issues gave him the Klineberg Award. The Academy of Management gave him the Eminent Scholar in International Management Award. The Federation of Associations in the Behavioral and Brain Sciences placed him on its list of honored scientists, which listed less than 100 psychologists. He was named Honorary International Fellow of the Center for Applied Cross-Cultural Research, Victoria University, Wellington, New Zealand in 2011. The International Academy for Intercultural Research gave him its Lifetime Contributions Award in Taiwan in 2004; the Society for Personality and Social Psychology gave him its Career Contributions Award in 2012 in San Diego, California.

He was a Ford Foundation faculty fellow (1964–1965), fellow at the Center of International Studies at Cornell University (1968–1969), a Guggenheim fellow (1972–1973), and a distinguished Fulbright professor to India (1983).

He was president of six Associations or Societies of Psychology. The Interamerican Society of Psychology, the International Association for Cross-Cultural Psychology, the Society for Personality and Social Psychology, the Society for the Psychological Study of Social Issues, the Society for Cross-Cultural Research, and the International Association of Applied Psychology.

After retirement in 1997, he continued publishing. His 2009 book *Fooling Ourselves: Self-Deception in Politics, Religion, and Terrorism* received the William James Award from the General Psychology division of the APA. The third edition of Jain, Triandis, and Weick, *Managing Research, Development and Innovation: Managing the Unmanageable*, was published in 2010. Bhagat, Triandis, and McDevitt, *Managing Global Organizations,*

appeared in 2013. His books were translated into Chinese, Farsi, German, Japanese, Russian, and Spanish. His publications span 60 years (1955–2015).

Beyond his professional accomplishments shines Harry Triandis' impeccable humanity. Michael Bond, another giant in the field of Cross-Cultural Psychology, wrote of Dr. Triandis, "After more than 40 years since we met, and across countless exchanges, Harry Triandis is still my hero; he has never disappointed me, nor I expect the many others whose lives and careers he has touched in his way, while on his way."

A brief synopsis of his majors works follows:

The Self

The 1989 paper "The Self and Social Behavior in Differing Cultural Contexts" explores how the identity of the self influences the way an individual interacts with their environment. Triandis identifies three different selves (private, public, and collective), whose complexities are shaped by cultural variables. The more complex the self, the higher probability it will be sampled, leading to behavior that is influenced by the sampled self. Triandis goes on to discuss how different aspects of a culture, such as individualism/collectivism, complexity, and tightness/looseness, dictate how the self is developed. The effect of ingroup/outgroup processes are also analyzed, showing that social behavior is more communal with an ingroup member, and that these ingroup/outgroup distinctions are exhibited more strongly in collectivist cultures. This publication was a pillar for examining the link between an individual's culture and their social behavior. The development of cultural aspects of the self remains a cornerstone for understanding cultural difference such as interdependent and independent self-construal (Markus & Kitayama, 1991).

Horizonal/Vertical Individualism/Collectivism

In Triandis (1995), he outlined the differences between individualistic and collectivist orientations where the former view themselves as independent in goals, needs, and desires from important groups, whereas the latter view themselves as part of and influenced by important groups like communities, families, workgroups, and nations. In 1998, Triandis and his former student, Michelle Gelfand, published an influential paper defining and empirically supporting a dichotomy within both individualism and collectivism. Triandis and Gelfand, in a four-part study, made their case for individualism and collectivism to be conceptually divided by their emphasis on horizontal or vertical social relationships. Horizontal individualism is characterized by a desire to be distinct from groups, while vertical individualism often relates to one's desired social status. In horizontal collectivism, there is an emphasis on one's common goals and similarities with each other, while in vertical collectivism the emphasis is on the goals of the ingroup. The four-part study included data collection in Korea, multi method data measurement and analysis, as well as comparisons of horizontal and vertical individualism and collectivism to previous work on components of these constructs. Triandis and Gelfand were able to not only demonstrate the reliability of horizontal and vertical measures of individualism and collectivism, but also showed the use of these conceptualizations in the exploration of previously unstudied aspects of culture and social identity.

Interpersonal Behavior

Triandis is well known for his pioneering work on his Theory of Interpersonal Behavior. He recognized that social factors and emotions played a key role in forming intentions and behaviors. He also noted the importance of past behavior on that of the present. In any situation, behavior, according to Triandis, is a function of one's intentions, their habitual responses, and the situational factors around them. Triandis conceptualizes intent as a sum of a number of affective, social, and attitudinal influences. Outside of its main role in defining social behavior, Triandis' theory has been used as framework for empirical analysis of various components related to social situations.

Culture Assimilator

Triandis, in the 1960s, was part of a team at the University of Illinois that was tasked by the Office of Naval Research with developing a training method that would "make every sailor an ambassador of the United States." This project produced what came to be known as culture assimilators (Fiedler, Mitchell, & Triandis, 1971). Triandis' previous work on culture and social behavior was pivotal in developing this program. Trainees are presented with situations where viewpoints between two different cultures do not align, and then asked to select explanations for why there is a problem. By receiving extensive feedback regarding culture theory (individualism vs. collectivism), trainees are able to think more similarly to individuals from another culture. The culture assimilators are able to train individuals to have better experiences in other cultures versus individuals who do not receive such training.

Fooling Ourselves

One of Triandis' more recent works is his book titled *Fooling Ourselves: Self-Deception in Politics, Religion, and Terrorism*. Triandis demonstrates the universality of self-deception, and how it can create harmful effects for both the individual and those around them. The role of culture in shaping this self-deception is a key point, particularly the roles of individualism, collectivism, and religion. Triandis also notes the tendency for people to deceive themselves with simple explanations about the world, rather than complex ones. However, the book highlights a paradox in self-deception, showing that people with religious rituals and beliefs are often happier than those without such ideas. Triandis goes on to explain how individuals can identify their own self-deceptions, and how to consider multiple dimensions of thought when drawing conclusions about the world.

Trimble, Joseph Everett

J. Douglas McDonald

University of North Dakota

The man known to legions of colleagues, students, and early career psychologists of color as "Uncle Joe" began his professional journey in 1969 by graduating with his doctorate in social psychology from the University of Oklahoma. Not surprisingly, his doctoral dissertation focused on the effects of socio-economic strata on American Indian men and the challenges they faced. He then completing postdoctoral fellowship research and training in mass communications, computer science, and cross-cultural counseling and learning. He began his academic career at Oklahoma City University, receiving tenured status in 1972. In 1975 he left the Great Plains for the Great Northwest with research associate postings at Battelle Human Affairs Research Centers, Portland State University, and the University of Oregon health sciences Center focusing on aging, human ecology, and social justice and change (Trimble & Medicine, 1976; Trimble, 1976). He then joined the faculty at Western Washington University in Bellingham Washington, where he remains as distinguished university professor, professor of psychology, focusing on a wide range of cross-cultural research and clinical issues (Trimble 1977; Trimble 1982; Trimble, 2005), including ethical consideration (Trimble & Fischer, 2005). While serving at WWU in these capacities, as well as developing and directing the center for cross-cultural research, Dr. Trimble also worked and collaborated with both University of Alaska campuses, dozens of Northwest area, and isolated Alaskan native communities researching the disastrous effects of poverty, alcoholism, and cross-cultural oppression (Trimble et al., 2014). He also served as fellow and visiting professor at Harvard University's Radcliffe Institute for Advanced Study in 2001.

Awards and Honors

His list of professional awards is extensive, including the Henry Tomes Award for Distinguished Contributions to the Advancement of Ethnic Minority Psychology from the American Psychological Association (APA), the International Lifetime Achievement

Award, Ontario Institute for Studies in Education, the lifetime achievement award from the APA Division 45, and the Janet E. Helms Award for Mentoring and Scholarship in Professional Psychology, to name a few.

Service

Dr. Trimble has generously donated his time and expertise to regional, community, and tribal organizations as well. His community service experiences demonstrate a broad range of compassionate and professional involvement for such groups as the Urban League of Oklahoma City, Oklahoma Indian Affairs Commission, multiple research institutional review boards, membership of over 20 community and professional governance and advisory boards and committees, and technical advisorships to an array of community and organizational units dedicated to social justice and community service, particularly those in Indian country.

Scholarly Works and Teaching

Dr. Trimble's formidable vita reflects his popularity as a speaker on areas of his considerable expertise, as well as his status as a respected statesman for American Indian and other social justice causes. Over 20 pages of selected entries documenting panel discussions, paper presentations, and most notably keynote addresses, speak to the popularity and respect he has earned amongst his peers during his career. Similarly, his selected listing of peer-reviewed publications, mostly relating to American Indian mental health and education, portray an impressive career of scholarly productivity. As of this writing, he has first authored over 80 peer-reviewed papers, 72 book chapters, and written or edited 23 books. He has also served as a reviewer or editor for 32 peer-reviewed professional journals. His words, thankfully recorded in both written and more lately digital/video archives (Trimble, 2017) have supported countless current and former students (including, proudly, this author), tribal members, and colleagues

Dr. Trimble has taught courses ranging from introduction to psychology, statistics, adolescent psychology, gender culture, and emotion, as well as 12 other courses across multiple university settings. He has chaired over 35 master's thesis committees, while serving on that many more as a member, and over a dozen doctoral dissertation committees. His support and mentoring of students of color, particularly American Indian graduate students, is commonly known.

Leadership

Dr. Trimble has often suggested (typically to, or about others) that the best measure of one's professional performance, as well as the level of respect shown from peers, is best represented in how often they have been elected or appointed to positions of leadership in their field. In this regard, he has certainly led by example. His governance and leadership in the

American APA is as lengthy as it is impressive. He holds fellow status in three APA divisions, serving on the Council of Representatives for two of them. He served on the Committee on Ethnic Minority Affairs (CEMA), the Board of Ethnic Minority Affairs, as well as four APA task forces. He was president of APA Division 45, and chaired five of that division's committees over the years. He chaired the APA Office of Ethnic Minority Affairs Committee on Ethnic Minority Recruitment and Retention and Training, and co-authored APA's Multicultural Guidelines. His various other professional committee and board leadership roles are simply too numerous to mention.

Legacy

As incredible, and even overwhelming, as Dr. Trimble's accomplishments are, they insufficiently herald the qualities and content of his character, spirit, and reputation. The word *Wawokiya* translates literally as "Helper" in Lakota. As with many translated American Indian words, the literal translation insufficiently conveys the entirety of its meaning. A true Wawokiya is honorable. They are selfless and humble. They are also reliable and powerful. The Wawokiya is typically a leader, a teacher, and a loyal friend. Dr. Trimble is the finest example of a Wawokiya many of his friends, colleagues, students, and relatives have ever known.

Personal Life

Dr. Trimble is a distinguished professor of psychology at Western Washington University in Bellingham, Washington. He resides there with his wife, Molly, where they have raised their three daughters – all distinguished professionals in their areas of endeavor. Dr. Trimble is an enthusiastic horticulturalist and fisherman. He was one of the founders of the Society of Indian psychologists (SIP), and recently received the American Psychological Foundation's Gold Medal Award for Lifetime Achievement in the Public Interest. His enlightening and entertaining TED talk is referenced below. In this author's estimation and hope – yet possibly not Molly's – he will probably never retire.

White, Joseph L

Adisa Ajamu

University of California, Irvine

Joseph L. White was born in Lincoln, Nebraska, on December 19, 1932, and was reared in Minneapolis. He eventually migrated west where he eventually enrolled at San Francisco State College in 1950, earning both his bachelor's and master's degrees, serving two stints in the Army, before subsequently attending Michigan State University to pursue a doctorate in clinical psychology. He took a PhD in clinical psychology in 1961, becoming the first African American to receive a doctorate in clinical psychology from Michigan State, and at the time becoming only the fifth African American in the country to hold a doctorate in clinical psychology.

Throughout his long and distinguished career, he received numerous awards and honors for his contributions to psychology in the service of social justice, for his work challenging erroneous and harmful psychological paradigms and understandings of ethnic minorities, for his work as a mentor and for his tireless efforts in advancing opportunities for African Americans and other ethnic minorities. Among those distinctions were: The Citation of Achievement in Psychology and Community Service presented by President Bill Clinton in 1994; the Janet E. Helms Award for mentoring and scholarship in psychology and education presented the annual Winter Roundtable on Cultural Psychology and Education at Columbia University in 2003; the University of California, Irvine Alumni Association's Extraordinarius Award in 2004.

In 2007 Joseph White was awarded an honorary Doctor of Laws degree from the University of Minnesota in 2007, the highest award conferred by the University of Minnesota, recognizing individuals who have achieved acknowledged eminence in cultural affairs, in public affairs, or in a field of knowledge and scholarship. A year later, he was acknowledged as the Alumnus of the Year from San Francisco State University in 2008. In 2015 he was awarded a Presidential Citation from the American Psychological Association for his distinguished work as a psychologist committed to social justice and equality. And in April 2017, Dr. White received the California Psychological Association's Lifetime Achievement Award.

He was the author and/or coauthor several foundational essays and books including: "Towards a Black Psychology" in *Ebony* magazine (1970), which is considered the seminal essay in the founding of the discipline of Black Psychology; *The Psychology of Blacks: An African American Perspective* (1984, 1990); *The Troubled Adolescent* (1989); *Black Man Emerging: Facing the Past and Seizing the Future in America* (1998) and the coauthor of *The Psychology of Blacks: An African Centered Perspective* with Thomas Parham and Adisa Ajamu (1999, 3rd ed.); *The Psychology of Blacks: Centering Our Perspective in an African Consciousness* with Thomas Parham and Adisa Ajamu (2011, 4th ed.) and coeditor with Michael Connors on *Black Fathers: An Invisible Presence in America* (2006).

Joe White: Psychologist as Social Justice Activist

Upon receiving his doctorate, Joseph White served as faculty and administration at Long Beach State University and later San Francisco College, his alma mater, and before eventually joining the University of California, Irvine. Early on in his academic career he would come to be known as one of the drum majors for social justice and trailblazer. At Long Beach State, he founded the Educational Opportunity Program (EOP) at CSULB in 1967, a model that would eventually be replicated throughout California and the United States, allowing tens of thousands of low-income minority students to enter and graduate from public and private colleges and universities.

At San Francisco State, as a professor and the dean of undergraduate studies he would stand with students during the Strike of 1968, which eventually produced the first Black Studies program in the country under the direction of Dr. Nathan Hare. In 1969, he was recruited to the University of California, Irvine, by founding Chancellor Daniel G. Aldrich Jr. as a professor in the Program in Comparative Culture and as director of the Black Studies Program. He would remain there until retirement in 1994. At UCI, his work continued with the founding UCI's first Counseling Center, the Cross-Cultural Center in 1974, the first of its kind in the nation, and work closely with the Speaker of the House of the California State Assembly, the Honorable Willie Brown to help get UCI's Medical School established.

Between his time at SFSU and his arrival at UCI he would also make two important contributions that would profoundly alter the landscape in the social sciences and the humanities and recalibrate the nation's trajectory and understanding of the relationship between social science, social justice, equality and public health. The first was his role in founding the National Association of Black Psychologists in 1968. The second was the seminal 1970 article published in *Ebony* magazine, asserting the need for new paradigms of psychological inquiry and explication to be rooted in the Black cultural experience, while noting that traditional psychological paradigms when applied to African Americans resulted in deficit and inferiority-based theories, which were inadequate in understanding the Black psychological experience. "Toward a Black Psychology" remains one of the most important essays is in the field of Black Psychology and the discipline of Black Studies.

Toward A Black Psychology: The Birth of ABPSI

In September of 1968, at the height of the Black Power movement, with Black America still reeling from the pain of the assassination of Dr. Martin Luther King and racial tensions over equal rights hanging ominously over the country, approximately 200 Black psychologists descended upon San Francisco for the American Psychological Association's National Convention in an effort to make their voices and that of Black America heard, once again.

There had been numerous efforts across the decades to get the APA to move towards a more just and egalitarian association, one that was fully welcoming to African American psychologists. As late as 1963, the Committee on Equality of Opportunity in Psychology (CEOP) an ad hoc of APA's Division 9, The Society for the Psychological Study of Social Issues (SPSSI) was "established (1) to explore the question of equal opportunity hiring practices relative to Black psychologists in professional and academic positions, (2) examine recruiting and selection of students for training in psychology, and (3) determine steps that may provide training and exchange opportunities for teachers and scholars at Black colleges and universities."

However, like previous efforts, leadership failed to pursue the concerns aggressively. By 1968, after years of delays and indifference on the part of APA, Black psychologists decided to take the matter into their own hands and, during the convention, several Black psychologists decided to sequester themselves in a room and lay out the preliminary framework for what would become the Association of Black Psychologists. Joseph White one of the members in the room, recalls the experience this way:

> When we got to San Francisco it was like a conscientiousness floating around ... people started talking in the hallways and then someone said, let's me in my room or Bob Williams room ... I can't remember, but the central topics of the meeting were plain and simple: We were dissatisfied with Psychology's exploitations and the white definitions for behavior that placed Black folks in a negative light. We were determined to construct some new definitions and terminologies ... We were mainly dissatisfied with APA because of the lack of graduate students in the nation's psychology programs ... also, the APA had taken no stand on the social revolution that was going on...all around them. *(Guthrie, 1998)*

In September 1968, emerging out of the need to respond to the "social revolution" going on around them and the responsibility those Black psychologists felt for the providing a better psychological frame to offer Black people hope, the Association of Black Psychologists was born and Joe White was among its founders. Charles Thomas and Robert Green were its inaugural co-chairs along with Earnestine Thomas, who served as the inaugural secretary. The association remains a leading voice in the psychological well-being and the mental liberation of Black people.

In the late 1960s, Joe White, standing at the crossroads between a Civil Rights Movement on the decline and a Black Power movement in ascendency, emerged as a powerful defiant voice of change and his ideas would help birth a discipline, providing psychological breathing space for Black people to develop, and, in the process, help usher in a fundamental shift in how ethnic, racial, gender, and sexual minorities were viewed, understood, and treated

in Western psychology. The reverberations of his impact can be felt in psychology, in public health, in Black Studies, in contemporary social justice movements for ethnic, racial, gender, and sexual minorities, the thousands of students who benefited from the creation of EOP and in the hundreds of students he mentored in his five-decade career in a process he affectionately called The Freedom Train.

Jones, James M

Jeffery Scott Mio

California State Polytechnic University, Pomona

James M. Jones is a leading voice in psychology on the issue of race, racism, prejudice, and discrimination. His book, *Prejudice and Racism* (Jones, 1972, 1997), is a classic in the field and has been held in high esteem by researchers in the field. He has been identified as one of the most influential Black psychologists in the field (White, Williams, & Majzler, 2011; Williams, 2008).

Early Life

James M. Jones was born in 1941 in Detroit, MI, to Arthur McCoy Jones and Eliza Marcella Hayes Jones. He is the elder of two children, with his sister, Judith Elizabeth Jones (Stacey) being born in 1944 (Jones, 2008). By the time his sister was born, the Jones family had moved from Detroit, MI, to Elyria, OH, where Jones attended Hamilton Elementary School, Franklin Junior High School, and Elyria High School.

   While Jones was raised in a housing project that was predominantly Black (95%), he did not personally feel he experienced overt racism among his mostly White classmates. Part of this was due to his successful academic endeavors, and part of this was due to his natural leadership tendencies, particularly in athletics. He was captain of his Little League baseball team and also his high school golf and basketball teams, along with being president of his Student Council. However, he was aware of racial inequities, such as not being able to bowl at the local bowling alley or not being able to rent a cabin on the lake during the summer. Such inequities gnawed at him, which motivated him to explore wider issues of racism.

Academic Influences

Dr. Jones graduated from Oberlin College in Ohio in 1963. There was a small Black student body there, but he did not really begin thinking of race relations or racism until after he graduated from college. While at Oberlin, he worked in Norman Henderson's behavioral

genetics lab. This experience introduced him to scientific psychology, but also confirmed that he was more interested in people than rats. When he traveled in Europe and also joined the workforce, he began thinking of race relations more and more. He went to college with the famous Kenneth B. Clark's daughter (Kate), and Clark became a role model after whom Jones wanted to emulate. He received his master's degree in psychology from Temple University in 1967, then he became the first Black student in Yale's PhD program in social psychology, graduating from Yale in 1970. By then, he had married his college sweetheart, Olaive Burrowes, and they had Shelly, their first of two daughters. Jones reported that his professors and classmates were very supportive, and he has remained friends with many of them throughout the years. In graduate school, Chuck Kiesler and Bob Abelson were mentors. Kiesler invited him to write a book on prejudice, which became his seminal work of *Prejudice and Racism,* published in 1972 and a revised second edition in 1997. This invitation came when he was in only his third year of graduate school and was before he had written his dissertation, so his supportive advisor was one of his principal influences in what was to become his signature issue. Moreover, many other Black scholars of the time were thinking along the same lines as Dr. Jones, so he found a very supportive environment for his ideas.

Employment History

Dr. Jones's first job was at Harvard University in the Department of Psychology and Social Relations. He remained there from 1970–1976, where he met and worked with many professors who became accomplished in their own right (e.g. a vice-chancellor at UCLA, President of Fisk University, a U.S. Solicitor General). During his stay at Harvard, he won a John Simon Guggenheim Fellowship. This award took him to Trinidad and Tobago to study humor – his dissertation topic. This experience led him to another one of his signature accomplishments, which was to develop his TRIOS model. TRIOS is an acronym for Time, Rhythm, Improvisation, Orality, and Spirituality, dimensions along which different cultures differ (Jones, 1979).

From Harvard, Dr. Jones took a job with a Black consulting firm in Washington, DC. When Dalmas Taylor decided to leave the Minority Fellowship Program (MFP) at the American Psychological Association (APA), he and Dr. Jones's former advisor, Kiesler, who was then APA's CEO, asked Dr. Jones to take over the MFP directorship, where he served from 1977–2005. There, he helped support hundreds of ethnic minority psychologists in their graduate studies, including those who became college administrators, major figures in multicultural psychology, and even an APA president. While serving as the director of the MFP, he simultaneously served as APA's affirmative action officer (1986–1991) and was the inaugural executive director of the Public Interest Directorate (1987–1991). During his time as executive director, he spearheaded a significant engagement with a variety of public interest issues which included two edited *American Psychologist* special issues – one on homelessness and one on HIV/AIDS. He also began his affiliation with the University of Delaware during this period (1981) where he has remained ever since, serving as chair of Black American Studies, director of the Center for the Study of Diversity, and ultimately earning the title of the Trustees Distinguished Professor.

Academic Impact

As identified earlier, Dr. Jones's two major impacts upon the profession have been on his writings on prejudice and racism and his TRIOS model. One of the major writers in the multicultural literature, Derald Wing Sue, has referred to Jones's book *Prejudice and Racism* (2nd ed.) as a must-read, as it was a definitive book on the topic. More recently, he has published *The Psychology of Diversity: Beyond Prejudice and Racism* (Jones, Dovidio, & Vietze, 2014), which is sure to become a classic in the field. This book goes beyond issues of racism and extends to differences in worldviews in the broader issue of diverse perspectives.

The TRIOS model identifies differences in the five dimensions of Time, Rhythm, Improvisation, Orality, and Spirituality. It was mainly developed to understand differences between those of African descent and White Americans, but it can be applied to people of a range of different cultural backgrounds. For example, with respect to time, some cultures tend to be future oriented, some past oriented, and some present oriented. Consequently, cultures that are future oriented may not appreciate the present enough because members of that culture are worried about what is next. Rhythm is a way of connecting one's psychological experience with the outside world to give meaning to the world. In African cultures, things like paddling a canoe or chopping a tree occur in rhythmic patterns. Improvisation is identified as both a coping mechanism and a means of personal and situational control.

Honor and Awards

Dr. Jones has had a distinguished career that has long been recognized. In 1999, he received the Lifetime Achievement Award from Division 45 (Society for the Psychological Study of Ethnic Minority Issues, later Society for the Psychological Study of Race, Culture, and Ethnicity) of the APA. He was twice recognized by Division 9 of APA (Society for the Psychological Study of Social Issues – SPSSI), first in 2001 as the recipient of the Kurt Lewin Memorial Award and then in 2009 as the recipient of the Distinguished Service Award. In 2004 he was elected president of SPSSI and led a delegation of behavioral scientists to South Africa to study truth and reconciliation, violence against women, and issues related to HIV/AIDS. In 2004, he received the Presidential Award from the Asian American Psychological Association for his advocacy of the development of Asian American psychologists, and he received the Distinguished Psychologist Award from the Association of Black Psychologists in 2007. For his long-time service to APA, he received the Distinguished Lifetime Contribution to Psychology Award from APA in 2011. In 2015, the National Multicultural Conference and Summit bestowed upon him the Distinguished Elder Award.

Personal Life

As stated earlier, Dr. Jones married his college sweetheart, Olaive Burrowes, and they had two daughters, Shelly Lovell Jones (Hairston), 1963, and Itenash (Nashe) Allegra Jones, 1970. Shelly ultimately became a medical doctor in anesthesiology, and Nashe became a marketing manager for Microsoft. Shelly has one child, Lowell James Hairston, who is the only grandchild.
